the surface of earth, or about the same as our atmosphere at an altitude of 80,000 ft. The composition of the Martian atmosphere is exceedingly uncertain but probably consists mostly of nitrogen, with smaller amounts of argon and carbon dioxide. Their partial pressures have been put at 19 mb. for N_2 , 2 mb. for A^{40} , and 4 mb. for CO_2 , with trace amounts of water vapour and oxygen. Other hypotheses give partial pressures differing considerably from these. The argon probably results from decay of the radioactive isotope of potassium (K^{40}). It is unfortunate that neither nitrogen nor argon has observable spectrum lines, so that their presence can only be inferred from analogy with the atmosphere of earth.

Mariner 4 followed an orbit that caused it to pass behind Mars, as seen from earth. As the spacecraft was passing behind the planet, there was a brief period when its tracking signal was traversing the Martian atmosphere. The signal faded out for somewhat the same reasons that the disk of the sun is dimmed at sunset. As the sun approaches the horizon the disk grows fainter mainly because of the scattering of its rays by air molecules. There is also some dimming that is due to unequal refraction (bending) of light from the disk. The effect of differential refraction is to deform the solar disk and reduce its size.

In the occultation experiment, however, differential refraction is the predominate cause of fading and weakening of the tracking signal. The changes observed in the signal showed that the Martian atmosphere is so rarefied that the surface pressure is only 1 or 2% of terrestrial atmospheric pressure at sea level.

SURFACE FEATURES

When viewed through a telescope of moderate power under favourable (good visual) conditions, Mars presents the appearance of a bright-reddish or tawny-coloured disk girdled by darker markings in the southern hemisphere which may at different times be blue-green, gray-green, or light grayish-blue. The true colour of these dark markings is difficult to determine since it is strongly influenced by contrast with the bright-reddish colour of the neighbouring regions. At one of the poles there is usually a white cap which may appear as the most conspicuous marking on the disk, depending upon the Martian season and the orientation of the planet relative to earth. During moments of exceptionally good seeing the observer also catches glimpses of detailed markings—small spots and specks and lines—which come and go so rapidly that it is impossible to set them down accurately in a sketch.

The bright-reddish areas which cover about three-quarters of the planet and which give Mars its characteristic fiery red colour are apparently uniform expanses of barren desert. The dark areas, which are situated mostly in the southern hemisphere, are called *maria* (seas), since they were once supposed to be actual bodies of water. The absence of bright reflected sunlight from the *maria*, as well as the detail occasionally visible in them, indicate that they consist of dry land similar to deserts.

An interesting observation of Mars when close was made by M. L. Humason and W. Baade with the 100-in. reflector on Mount Wilson when seeing conditions were "excellent, almost perfect." These observers, although experienced professional astronomers, were not experienced in observing planets. Their observations were made visually at the cassegrain focus of the telescope through a red filter. The outstanding feature was the sharp edge of the *maria*, which looked black and contrasted sharply with the bright regions. Both men tried to glimpse the canals but were unable to see them. They agreed that in the bright regions there appeared to be short "grooves," as nearly as they could describe them.

Polar Caps.—It was suggested by the British physicist George

TABLE IV.—Physical Characteristics of Mars*

	Earth = 1	km.	mi.
Equatorial diameter	0.5353	6,828	4,243
Polar diameter	0.5296	6,756	4,198
Equatorial diameter (solid surface)	0.5292	6,749	4,194
Polar diameter (solid surface)	0.5252	6,700	4,163
Velocity of escape	—	5.05 km/sec	3.14 mi/sec
Area (solid surface)	0.278		
Volume (solid surface)	0.146		
Mass	0.108		
Density	0.737		
Surface gravity	0.38		
Atmospheric pressure at surface	0.01-0.02		
Position of north pole (1905)			
Right ascension	316.55° = 21 hr. 06.2 min.		
Declination	+ 52.85°		
Position of north pole (1970)			
Right ascension	316.99° = 21 hr. 08.0 min.		
Declination	+ 53.08°		
Inclination of equator to orbit	24.936°		
Polaris of Mars	Alpha Cygni (Deneb)		
Flattening	0.0103		
Visual albedo	0.159		
Visual magnitude at mean opposition	1.52		
Symbol (spear and shield)	♂		
Martian sidereal day	24 hr. 37 min. 22.6689 sec.		
Martian mean solar day	24 hr. 39 min. 35 sec.		
Magnetic moment	<0.001 of earth's		

*These data are taken mostly from *The Physical Ephemeris of Mars*, Memorandum RM-3999-NASA (Jan. 1964), and *Geometric and Photometric Parameters of the Terrestrial Planets*, Memorandum RM-4000-NASA (March 1964), by G. de Vaucouleurs.

Johnstone Stoney, in 1898, that the polar caps consist of frozen carbon dioxide gas (Dry Ice) rather than snow and frost. Radiometric measures, as noted above, indicate a temperature of -70°C (-94°F) at the polar caps, but carbon dioxide under the atmospheric pressure on Mars would not solidify unless the temperature was about -144°C (-227.2°F). Measures by Kuiper in the infrared spectrum show that the polar caps reflect light like terrestrial snow. Snow becomes almost "black" beyond wavelength 1.5μ , and almost completely black beyond 2.0μ , but Dry Ice remains "white" out to 2.5μ . From his tests Kuiper concluded that the Martian polar caps are not composed of frozen carbon dioxide but are almost certainly composed of water (H_2O) frost at a temperature much below 0°C (32°F).

The melting polar cap in spring is surrounded by a dark band that remains in contact with the shrinking cap. This band was once regarded as marshy ground formed from the water of the melting polar snows, but it is extremely doubtful that there is enough water to form such a region. When viewed under the best conditions the band is seen to be discontinuous, broken up into individual spots. It appears to be part of the general wave of darkening in the Martian spring that spreads from the polar cap, over the *maria*, down to and beyond the equator.

Deserts.—Kuiper compared the reflectivity of the red Martian deserts with that of red soil and red rock collected in Oklahoma, Texas, and Arizona. He found the reflectivity of these specimens to be quite different from that of the red regions of Mars. However, the reflectivity of a brownish, fine-grained felsite closely matched that of the Martian deserts. He concluded, there-

fore, that the deserts of Mars consist of igneous rock similar to felsitic rhyolite.

Dollfus advanced a more convincing theory, based on polarimetric and photometric studies of the red regions. He found that limonite properly pulverized reproduces the polarization and brightness curves of the deserts surprisingly well. The evidence from the polarization measures is particularly strong, since very few substances have a polarization curve resembling that of the Martian bright areas. Dollfus' early work agreed with that by Carl Sagan (1965), who found within the range of observational uncertainty that laboratory diffuse reflection spectrophotometry support the identification of powdered ferric oxides as a principal constituent of the Martian bright areas.

Maria.—As the polar cap in the southern hemisphere shrinks during the Martian spring, the *maria* begin to darken and become more conspicuous, first near the pole, then gradually spreading toward the equator and even over into the opposite hemisphere. In the autumn some of the *maria* turn brown, brownish purple, and carmine, while others are but little affected. There can be little doubt that seasonal changes occur in the *maria*, but they are more complex than was generally believed. These changes suggest the growth and decay of vegetation, and the idea that water vapour, not as clouds but as an invisible gas, spreads from the pole toward the equator causing plant life to spring up in its wake.

If the *maria* consist of vegetation, it must be of a type entirely different from that on earth, and exceedingly hardy to withstand the freezing Martian nights. Plants of the type known on earth need oxygen for respiration, but there is no free oxygen present in the Martian atmosphere.

Evidence that the *maria* consist of some kind of organic substance was obtained by Sinton at the oppositions of 1956 and 1958. All organic molecules possess strong absorption bands near 3.4μ , the wavelength of the carbon-hydrogen bond resonance. Measures on the spectra of Mars in this region indicate the probable presence of these bands. This evidence, together with the seasonal changes in the *maria*, made it seem highly probable that vegetation of some sort exists on Mars. But D. G. Rea (1963), on the basis of laboratory investigation, considers the identification of the infrared bands in the Mars spectrum with organic molecules to be at least doubtful, as they can be attributed just as well to absorption by inorganic molecules. (See *Life on Mars?* below.)

In polarimetric and photometric studies of the *maria* made after 1947, Dollfus found that the *maria* have a powdery surface structure similar to that of the bright desert regions but more absorbent. He was able to simulate the variations in brightness of the *maria* in the laboratory by mixing pulverized limonite (HFeO_3) with a powder of very absorbing grains. Similar effects were obtained by partially covering the limonite with these grains and, vice versa, by partially covering these grains with limonite.

The polarization of light from the dark regions of Mars is not unlike that from the bright deserts, but it varies with the change of seasons. This variation suggests a seasonal change in the nature of the surface, though on a microscopic scale. Physical or chemical changes in minerals are not alone sufficient to explain such changes. Dollfus found that certain algae, small lichens, or minute mushrooms, when sprinkled on pulverized limonite, showed a polarization curve similar to that of the Martian dark spots. On earth such microscopic organisms are generally creatures with a great power of adaptation. Their absorbent character suggests a superficial coloured pigment that offers protection against cold or excessive radiation by selective absorption of light.

Crustose lichens are among the hardiest plants on earth, and exhibit the same general colours and reflection spectra as the *maria*; their size is consistent with the postulated size of the Martian organisms (calculated from the total amount of water on the planet). Moreover, lichens are known to tolerate extreme climatic conditions.

On the other hand, Frank B. Salisbury has presented several objections to the theory that the Martian *maria* are composed of lichenlike organisms. First, it is unlikely that lichens could subsist in an atmosphere of low oxygen content like that of Mars. Lichens do not change colour with the seasons as do the *maria*. Also, cru-

those lichens are extremely slow growing and are sparsely distributed. In 1954 a new dark area about the size of Texas was first observed; it had developed sometime within the two years since Mars had last been viewed. If this area was due to vegetation, it would seem that plant life on Mars is not barely surviving but actively flourishing. An inorganic explanation of the maria may be considered along with the lichen hypothesis. Kuiper made observations of Mars in 1954 and 1956 with the 82-in. reflecting telescope of the McDonald Observatory, paying special attention to the colours of the bright and dark areas. The colours, which were expected to be green in the Martian spring, were, instead, a neutral gray. The lack of vivid coloration suggested the possibility that the maria might be lava fields similar to the broad dark expanses on the moon. As a working hypothesis Kuiper suggested that the maria were lava fields partially covered by some very hardy vegetation.

In 1954 the astronomer Dean B. McLaughlin had already advanced an inorganic theory of the composition of the maria. He suggested that they are deposits of volcanic ash that had been weathered to a soil in which epidote and chlorite abounded, thereby accounting for the green colour. The seasonal darkening of the maria would result from the moistening of the surface minerals rather than from a chemical change. From observations that the maria terminate in funnel-shaped markings pointing north into the deserts, McLaughlin concluded that the tips of the funnels might be the sites of volcanoes whose ash had been carried by the winds and deposited in the patterns that form the maria. Since the winds blowing to the southern hemisphere are much stronger than those blowing to the northern hemisphere, the maria would thus be expected to form primarily south of the Martian equator. In fact, most of the maria are south of the equator.

Although the atmosphere of Mars today probably consists mostly of nitrogen, long ago a considerable quantity of oxygen may have been present. The oxide-of-nitrogen hypothesis seeks to account for practically all the surface phenomena observed on Mars by oxides of nitrogen in various states, mainly nitrogen dioxide (NO_2) and nitrogen tetroxide (N_2O_4), which may combine to form nitrogen peroxide (C. C. Kiess, S. Karrer, and H. K. Kiess, 1960, 1963). On this hypothesis life on Mars would be impossible, since nitrogen peroxide is poisonous to both plants and animals. The gas is unstable, continually undergoing a dreary process of decomposition and regeneration in which nothing is created and nothing destroyed. Several investigations of the Martian spectrum put an upper limit to the abundance of NO_2 of 1 mm.atm., which is insufficient to explain phenomena such as the polar caps, the darkening of the maria in spring, colour changes, etc. Sagan remarked that the amount of NO_2 above Los Angeles has been found to be 3 mm.atm., three times as much as the upper limit on Mars.

Most astronomers favour a vegetative hypothesis despite the difficulties it encounters. E. J. Öpik presented an effective argument for this theory: the maria must have regenerative powers, or they would have been obliterated ages ago by the dust of the deserts.

The principal topographic features revealed on Mars by Mariner 4 do not correspond to the type that would be produced by stress and deformation originating within a planet, as is the case with earth. Earth is internally dynamic, creating mountains and continents, but Mars has evidently long been inactive. Lack of internal activity is consistent with the negative result of the magnetometer experiment, which failed to detect evidence of a Martian magnetic field. The results show the magnetic moment of Mars is less than one-thousandth that of earth. The results were also negative insofar as detection of any charged particles associated with the planet were concerned.

A casual inspection of the Mariner 4 photographs is enough to show that the surface of Mars resembles the moon more than the earth. About 70 craters were counted on photographs 2 to 15, inclusive, which cover about 1% of the planet's surface. On the doubtful assumption that this 1% is representative of the surface as a whole, there would be approximately 7,000 craters on Mars. The pictures show well-defined craters ranging from 3 to 25 mi. in diameter, in addition to circular markings up to 75 mi. in diameter

resembling the great walled plains on the moon. Most of the Martian craters have flat, smooth floors, although a few show central peaks like some of the lunar craters. The crater walls rise a few hundred feet above the surrounding surface and reach depths of several thousand feet below the crater rims.

Canals.—Discovery of the Martian markings designated as canals was made by G. V. Schiaparelli (*q.v.*) at the exceptionally close opposition of 1877. Schiaparelli described these markings as *canali* ("channels" or "canals"). Translated into English as canals, the word erroneously suggested that these channels were artificial waterways constructed by intelligent beings. In 1892 W. H. Pickering discovered a new feature of the canals which he called an oasis, a small round spot at the junction of several canals.

All observers agree that Mars shows a vast amount of fine detailed markings so complex as to be impossible to represent properly in a drawing. The markings come and go so rapidly with fluctuations in the seeing that even the best photographs fail to show the fine details that can be glimpsed by the eye.

Most astronomers have never been able to see canals on Mars and hence are naturally skeptical of their existence.

Judging from the maps which Schiaparelli made at the six oppositions from 1877 to 1888, the canals must have appeared to him as narrow dark lines extending across the deserts. Lowell in 1894 described them as a "network of fine straight, dark lines . . . either absolutely straight from one end to the other, or curved in an equally uniform manner."

E. M. Antoniadi stated that in good seeing, the canals appeared to him as continuous lines, but in moments of the very finest seeing they broke up into a discontinuous series of lines and dots.

R. J. Trumpler's remarks about the canals (on the basis of observations made in 1924 and 1926 with the 36-in. refractor at Lick Observatory) are of value, as representing the views of a careful and conservative observer:

The network lines, the so-called canals, are not a well-defined class of similar objects, but vary greatly in visibility, width, and definition. Some of them, like *Nectar*, *Cerberus*, *Thoth*, *Nepenthes*, are temporarily so wide as to resemble the dark areas. Practically every step of transition between these broad bands and the finest most difficult canals is represented.

The canals as a rule, even the fainter ones, do not appear quite sharp but rather as diffuse hazy shadings. Sometimes they change in intensity along their course, and occasionally they even break off abruptly without reaching an endpoint. . . . In the dark areas the network is also present, but here the lines mostly become broad dark bands while the spots appear as diffuse condensations of shading. There are many reasons indicating that the framework structure of the dark areas is of the same topographical character as the network (canal) system of the normal surface. . . . The network exhibits a great deal of irregularity and does not make the impression of artificiality. Although a certain tendency to straightness or directness of line in the canals cannot be denied, it seems nevertheless possible to interpret the network by natural geological features of the crust of the planet. (R. J. Trumpler, "Visual and Photographic Observations of Mars Made at the Opposition of 1926," *Publications of the Astronomical Society of the Pacific*, vol. 39, p. 103, 1927.)

In 1939 Edison Pettit of the Mount Wilson Observatory began a series of drawings of Mars using a 6-in. Clark refractor. He undertook the work as a matter of self-education, with the intention of studying the seasonal changes. He had never been able to see the canals, and had concluded that they were visible only to a special type of eye, and that his eyes were of the great majority that could not see them.

Early one morning, while sketching the planet, a canal suddenly appeared and within a few seconds another. Within two hours he was able to see two more, sometimes all four being visible at once. On succeeding nights he was able to see the four canals again and some additional ones. In the following two months he made drawings of 40 canals, each identified three times before being put on a final drawing. On the best nights there were moments of "superseeing" when the whole canal pattern would flash out for a second or two. Very rarely was this interval as long as four or five seconds. The colour of the canals was an olive green, the same tint as the maria at that time.

On June 3, 1956, when Mars was at a distance of 75,000,000 mi., R. S. Richardson observed Mars under very favourable seeing

conditions with the 60-in. reflecting telescope on Mount Wilson. The canals appeared to be simply narrow extensions of the maria into the deserts, and were of the same colour as the maria. The markings did not have an artificial appearance, but gave the impression of being some natural surface feature. Richardson seems to have seen the canals in much the same way as Trumpler saw them in the description cited above.

On the other hand, Kuiper maintained, "I have never seen a long, narrow canal nor a network of 'fuzzy canals.' I am personally convinced that the objective evidence which has led to this concept has been misinterpreted and erroneously represented on drawings" (Gerard P. Kuiper, "On the Martian Surface Features," *Publications of the Astronomical Society of the Pacific*, vol. 67, no. 398, Oct. 1955). Kuiper found that there was no evidence anywhere on the planet of a distinctly geometrical pattern; nor of a systematic streakiness in relation to the planetary coordinates (though in a given mare some streakiness may be observed). To him the dimensions of the patches appeared quite random and natural—and the representation of the many oases of roughly uniform size he considered definitely wrong.

An observation of Mars made by G. E. Hale and his associates at the 60-in. telescope on Mount Wilson on Nov. 3, 1909, has been quoted so often, and has come to be of such critical importance in the history of the canals, that it deserves comment. Mars was observed that night under excellent seeing conditions with a magnification of 800. Hale in a letter says: "So far as any of us could make out, there is not a trace of geometrical structure on the planet, nor any narrow straight canals."

All experienced observers of Mars are agreed that the visibility of the canals depends upon the Martian season. They first appear clearly in the southern hemisphere about early spring corresponding to April 1 (northern style season), and by the middle of June little is left of them. Very few canals are visible in the southern hemisphere from late summer through winter. Hale's observation was made in Martian midsummer corresponding to terrestrial date July 23. It is therefore not surprising that he and his colleagues failed to see any canals that night.

There is no trace of the canals on the Mariner 4 pictures. This is not so surprising, however, when one considers the nature of the photographs themselves and the circumstances under which they were taken. Photographs 8 to 13, inclusive, are all of the Mare Sirenum where a canal would be difficult to discern against the dark background. The first seven photographs, taken over the bright areas, are crossed by several well-known canals: Erebus on no. 2, Orcus on no. 3, and Avernus on no. 5. Each photo shows an area very approximately 300 mi. on a side. As a mean between various estimates, a width of about 50 mi. for a canal can be assumed. On the scale of the photographs the canals would not appear as dark lines but rather as a short section of a broad band. Such a marking would not show on the photographs unless it stood out in strong contrast to its surroundings. But one would expect the canals to be dim because the photographs were taken when the season was midwinter in the southern hemisphere and the canals seldom appear to advantage until the southern spring.

LIFE ON MARS?

Plant Life.—Despite the daily extremes in Martian temperature, the absence of oxygen from the atmosphere, and the low humidity, observational evidence from several sources indicates the presence of life in the maria. Some interesting work on this subject was carried out by G. A. Tikhoff of the Academy of Sciences of the U.S.S.R. and his co-workers near the Arctic circle in the eastern Soviet Union, where conditions except for oxygen are scarcely less rigorous than those on Mars. The purpose of the project was to study plants growing under conditions resembling as nearly as possible those on Mars. The investigation proceeded from three basic assumptions: that the laws of life in the universe are identical in essence but differ in their manifestations; that the living organism is exceedingly adaptable to external conditions; and that plants possess optical adaptations to external conditions.

One of the objections to the presence of green plants on Mars is that the maria do not reflect light as chlorophyll does. Chloro-

phyll, the green colouring matter in plants, shows an absorption band at about $\lambda 6,700$, and reflects light strongly in the infrared beginning at about $\lambda 7,000$. But the maria reflect red and infrared equally well.

Tikhoff's group found that, as a general rule, plants growing under conditions of extreme cold do not reflect as much light as those growing in milder climates. Evergreens, for example, were found to reflect about half as much of the red rays in winter as in summer. About half the radiant energy from the sun is contained in the infrared region of the spectrum. Ordinarily, green plants reflect these rays strongly. But in an extremely cold climate the plants protect themselves from the cold by absorbing as much as possible of the radiant energy from the sun. They not only absorb much of the infrared radiation of the sun but a considerable portion of the red, orange, and yellow light as well. Therefore, plants growing in excessively cold climates do not show the characteristic absorption band of chlorophyll in the red simply because the radiation throughout this whole region is absorbed. Plants growing in the Arctic usually appear darker or "bluer" than plants growing in a warmer climate because they reflect principally violet, blue, and green light; whereas plants in warmer climates reflect yellow and some orange. From their observations on the Pamir plateau in the Arctic, the climate of which is hardly less severe than that of Mars, Tikhoff and his colleagues concluded that the low Martian temperatures would not necessarily be fatal to plant life.

From considerations of the maria, Salisbury concluded that life as it is known on earth could not survive the rigours of the Martian climate. But he offered two biological possibilities: that life forms, essentially similar to those known on earth, have become adapted to the planet; or that some other form of life, a parabiology, accounts for the markings on Mars.

Animal Life.—Existence of animal life on Mars is much less likely than plant life. It is unlikely that higher forms of animal life could exist in such a cold, arid, and oxygenless world. Only the lowest types of animals, with little need of oxygen or water, would be able to survive. Information on this point has been obtained experimentally by subjecting terrestrial microorganisms to an environment closely simulating that on Mars (E. Packer, S. Scher, and C. Sagan, 1963). From their results these workers stated their conclusions as follows:

We may have some confidence that terrestrial microorganisms will survive the inclemency of the Martian environment and that under supercooled conditions at temperatures above -20°C some bacterial growth can be anticipated. Growth will depend in part on the availability of water and organic material on and near the Martian surface. The likelihood that many terrestrial microorganisms can survive on Mars has, of course, no rigorous implications for the likelihood of indigenous life on that planet. Yet it does demonstrate that evolutionary tractable biological mechanisms exist for survival and growth under contemporary Martian conditions, and suggests that organisms slowly evolving from the more clement conditions in the ancient Martian past may have even greater capability for dealing with the apparent rigours of the Martian environment.

Mariner 4 was not designed to secure information regarding life on Mars. On the evidence of the photographs, the question is still open. But the moonlike uneroded aspect of the surface shows that the planet has never had an extensive atmosphere or enough water to form seas and oceans. High forms of animal life could not develop under such unfavourable conditions, but plant life is not ruled out. The seasonal changes in the maria are yet to be explained. The new dark area that developed in the Thoth region between 1952 and 1954 begins to loom as an observation of major importance. Thoth was not a feature barely visible like the canals but was an area about the size of Texas and was easily visible to anyone with a 6-in. telescope.

Human Habitability of Mars.—By careful preparation a man could undoubtedly survive on Mars. But he would be living in a hostile, alien environment where the slightest mishap could be disastrous. Atmospheric pressure at the surface appears to be much lower than was formerly supposed. To carry on respiration a pressure suit and oxygen equipment would be necessary. Many reactions so familiar to man on earth that they are taken as a matter of course would be impossible on Mars or would proceed very slowly. A man out on the open surface could not light his

pipe or start a fire. Metal would not rust. Under the reduced pressure water would boil away so rapidly it would be useless for cooking purposes. None of the natural sources of energy, such as coal and oil, is available on Mars. Solar radiation would be weak and undependable. To establish a base on Mars, suitable nuclear reactors would first have to be developed to maintain it.

Because the Martian atmosphere is bombarded continually by the full flux of cosmic rays and full fluxes of solar flare particles, the radioactive products of the disintegrations present differ from those on earth and probably are somewhat more intense relative to the density of the atmosphere. Recent evidence indicates that ultraviolet rays penetrate the Martian atmosphere and reach the planet's surface, thus creating a radiation hazard for man.

SATELLITES

The two moons of Mars were discovered by Asaph Hall of the U.S. Naval Observatory in 1877. That year was especially favourable for such a search, as the planet was within 34,800,000 mi.

TABLE V.—*Satellites of Mars**

	Phobos	Deimos
Discoverer	Asaph Hall	Asaph Hall
Date of discovery	Aug. 17, 1877	Aug. 11, 1877
Distance from centre of Mars (radius of Mars = 1)	2,743	6,891
Distance from centre of Mars	5,820 mi. (9,366 km.)	14,615 mi. (23,520 km.)
Sidereal period	7 hr. 39 min. 13.85 sec.	30 hr. 17 min. 54.87 sec.
Inclination of orbit to equator of Mars	0° 57'	1° 18'
Orbital eccentricity	0.0210	0.0028
Approximate magnitude at mean opposition distance	11	12
Estimated diameter	10 mi. (16 km.)	6 mi. (10 km.)

*These data are taken mostly from the *Explanatory Supplement to the American Ephemeris and Nautical Almanac* (1961).

of earth on Sept. 5, the closest approach in 30 years. Other observers had searched in vain for a satellite of Mars, but Hall believed the new 26-in. refractor of the Naval Observatory should be able to detect a companion of Mars, if one existed.

However, he was almost ready to give up the search as hopeless when he sighted a suspicious object near the planet on the night of Aug. 11. Clouds prevented further observations until Aug. 16, when the object was sighted again and found to be moving at the same rate as Mars, thus establishing its identity as a satellite. The following night Hall found another object closer to the planet than the first one; it moved so rapidly that he thought at first Mars must have several inner moons. By keeping watch continually throughout the nights of Aug. 20–21 he satisfied himself that there was but one inner moon. Hall named the outer satellite Deimos (Terror) and the inner one Phobos (Fear), after the horses that drew the chariot of the war god Mars. The discovery of these satellites was of great practical importance as it enabled astronomers immediately to get an accurate value for the mass of Mars.

Phobos is so near the planet that it revolves around Mars in less than one-third of the rotation period of Mars. To an inhabitant of Mars, Phobos would rise in the west and set in the east, making two apparent rotations in a day. The period of Deimos is six hours longer than a Martian rotation. Its apparent motion around the planet would be so slow that more than two days would elapse between rising and setting, and setting and rising.

Phobos and Deimos are too small to present a disk even in the largest telescopes, and so their diameters cannot be measured directly. However, if an assumption is made about their albedos (overall reflecting power of their surfaces) their diameters can be calculated from their apparent brightness. Thus, if the satellites are assumed to have the same albedo as Mercury, the diameter of Phobos is 10 mi. and that of Deimos is 6 mi. But if it is assumed that they have the same albedo as Mars, the diameter of Phobos is about 8 mi. and of Deimos, 5 mi.

In 1959 I. S. Shklovskiy suggested that Phobos is a hollow sphere, and therefore of artificial origin. This startling hypothesis was made in an attempt to explain the apparent increase in the mean motion of Phobos reported in 1954 by F. J. Kerr and F. L. Whipple. If there is an appreciable Martian atmosphere 3,700 mi. above the surface at the orbit of Phobos, it would be more effective

in changing the motion of a body of negligible mean density, such as a thin shell satellite, than a solid body of the same size.

Tentative results obtained by G. F. Schilling (1963) indicate the Martian atmosphere at 3,700 mi. may be of sufficient density to produce the acceleration in the mean motion of a solid satellite. Some authorities question the reality of this acceleration, as well as the reliability of the observations from which it was derived. Until more and better data become available on this problem, hypotheses as to the constitution of Phobos seem futile.

(W. H. WR.; R. S. RN.)

MARSCHNER, HEINRICH AUGUST (1795–1861), German composer who helped to establish the style of German romantic opera, was born at Zittau, Saxony, on Aug. 16, 1795. He studied at Leipzig and about 1815 met Beethoven in Vienna. Weber produced his *Heinrich IV und d'Aubigné* in 1820 at Dresden, where Marschner was later appointed director of the opera. In 1827 he was appointed director at Leipzig, where in 1828 he successfully produced his romantic opera *Der Vampyr* and the following year *Der Templer und die Jüdin* on a libretto based on Sir Walter Scott's *Ivanhoe*. In 1831 he became director at Hanover and on May 24, 1833, he produced his more successful opera, *Hans Heiling*, at Berlin. Between 1836 and 1863 he produced five further operas, among them *Kaiser Adolf von Nassau* (1845), conducted by Wagner. None of these, however, achieved the success of his earlier works. He died at Hanover on Dec. 14, 1861.

Marschner's operas illustrate the preoccupation of early romantic opera composers with supernatural subjects. Aspects of his style, notably his brilliant orchestration, were influenced by Weber.

See H. Gaartz, *Die Opern Heinrich Marschners* (1912).

MARSEILLAISE, LA, the French national anthem. It was composed in one night (April 24, 1792), by Claude Joseph Rouget de Lisle, a captain of engineers who was also an amateur musician. After the declaration of war with Austria on April 20, 1792, the need of a marching song for the French was expressed by P. F. Dietrich, the mayor of Strasbourg, where Rouget was quartered. The hymn, originally entitled *Chant de guerre pour l'armée du Rhin*, was Rouget's response. Sung with enthusiasm by the volunteers from Marseilles on their march to Paris and at their quarters in the Faubourg St. Antoine, it came to be called "La Marseillaise."

"La Marseillaise" was accepted as the French national anthem by the Convention in a decree passed on July 14, 1795. It was banned by Napoleon during the empire and by Louis XVIII on the second Restoration (1815) because of its revolutionary associations. After the July revolution of 1830 it was again authorized. Napoleon III banned it and it was not reinstated till 1879. In 1887 Gen. George Boulanger, then minister of war, set up a commission under Ambroise Thomas to prepare a definitive edition of the music. It is now generally agreed that Rouget de Lisle wrote both the words and the music, though many composers, including Grétry and Gossec, later made improvements in it.

See L. Fiaux, *La Marseillaise* (1918).

MARSEILLES (French MARSEILLE), a city and chief seaport of southern France, the capital of the *département* of Bouches-du-Rhône. It lies 219 mi. S. by E. of Lyons and 534 mi. S.S.E. of Paris by railway. Pop. (1962) 767,146.

History.—The colony of Massilia (Massalia) was founded by Greek mariners from Phocaea (in Asia Minor) about 600 B.C.; probably Phoenicians had settled at Marseilles before the Greek period. In 542 B.C. the fall of the Phocaean cities before the Persians probably sent new settlers to Massilia and cut it off from close connection with the mother country. Isolated amid alien populations, the Massilians maintained themselves by prudence and by vigilant administration of their oligarchical government.

Their colonies spread east and west along the coast from Monaco to Cape St. Martin in Spain, carrying with them the worship of Artemis. The inland trade, in which wine was an important element, can be traced by discoveries of Massilian coins across Gaul and through the Alps as far as Tirol. In the 4th century B.C. the Massilian Pytheas visited the coasts of Gaul, Britain and Germany; and Euthymenes is said to have sailed down the west coast of Africa as far as Senegal. The great rival of Massilian trade was Carthage, and in the Punic wars the city took the side of Rome, and was rewarded by Roman assistance in the subjugation of the native tribes of Liguria. In the war between Caesar and Pompey, Massilia took Pompey's side and in 49 B.C. offered a vain resistance to Caesar's lieutenant Trebonius. In memory of its ancient services the city was left as a *civitas libera* ("free city") but its power was broken and most of its dependencies taken from it. Thereafter Massilia has little place in Roman history; it became for a time an important school of letters and medicine, but its commercial and intellectual significance declined. The town appears to have been Christianized before the end of the 3rd century.

After the ravages of successive invaders, Marseilles was re-peopled in the 10th century under the protection of its viscounts. The town gradually bought up their rights, and at the beginning of the 13th century was formed into a republic, governed by a *podestat*, appointed for a term of one year, who exercised his office in conjunction with 3 notables and a municipal council composed of 80 citizens, 3 clerics and 6 principal tradesmen. The higher town was governed by the bishop, and had its harbour at the creek of La Joliette, which at that period ran inland to the north of the old town. The southern suburb was governed by the abbot of St. Victor, and owned the Port des Catalans. Situated between the two, the lower town, the republic, retained the Vieux-Port (old harbour) and was the most powerful of the three divisions. In 1245 and 1256 Charles of Anjou, count of Provence, whose predecessors had left the citizens a large measure of independence, established his authority above that of the republic. In 1423 Alfonso V of Aragon sacked the town but King René, who had made it his winter residence, caused trade, arts and manufactures to flourish again. On the incorporation of Provence in the kingdom of France in 1481, Marseilles preserved a separate administration directed by royal officials. Under Francis I, Charles, duc de Bourbon, vainly besieged the town with the imperial forces in 1524 and 1536. During the wars of religion, Marseilles took part against the Protestants, and long refused to acknowledge Henry IV. The loss of the ancient liberties of the town brought new disturbances under the Fronde, which Louis XIV came in person to suppress. He entered the town by a breach in the walls and afterward had Ft. St. Nicolas constructed. Marseilles repeatedly suffered from the plague, notably in 1720-21.

During the Revolution the people rose against the ruling aristocracy. The city gave its name to the French national anthem (see MARSEILLAISE, LA). In the Terror the people of Marseilles rebelled against the Convention, but were promptly subdued. The wars of the empire, by dealing a blow to their maritime commerce, excited the hatred of the inhabitants against Napoleon, and they hailed the return of the Bourbons and the defeat of Waterloo. The prosperity of the city received a considerable impulse from the conquest of Algeria and from the opening of the Suez canal. During World War I part of the harbour became a British base, and many Indian, Australian and African troops passed through, and, after the Armistice, an American embarkation camp was established. In World War II Marseilles was occupied by the Germans from Nov. 1942 until it was liberated in Aug. 1944 by the French 3rd infantry division under Gen. Goisard de Montsabert. To spare the population, he besieged the city without bombing it. When U.S. soldiers returned home, in 1946, more than 1,000,000 embarked from Marseilles.

The Town.—Marseilles is situated on the Gulf of Lions on the eastern shore of a bay protected to the south by Cape Croisette but open toward the west. The city is built on undulating ground and the southwestern and most aristocratic quarter covers the slopes of the ridge crowned by a fort and the church of Notre-Dame-de-la-Garde and projecting westward into the bay to form

a protection for the harbour. The newest portion lies on the southeastern slope of the ridge, which is better protected than most of the other quarters from the mistral (a cold northerly wind), and where in summer the temperature is always a little lower than in the centre of the town. From the old harbour, which opens on the west to the Gulf of Lions, the famous boulevard La Canebière, the artery of the city's life, leads east-northeast.

The old town of Marseilles is bounded on the west by the Joliette basin and the sea, east by the Cours Belsunce, south by the northern quay of the old port, and north by the Boulevard des Dames. It consisted of a labyrinth of steep, dark and narrow streets inhabited by a seafaring population. On Jan. 24, 1943, the Germans evacuated the entire district on the edge of the port and destroyed it with explosives. Subsequently a new residential district was built there.

The entrance to the old harbour is defended by Ft. St. Jean on the north and Ft. St. Nicolas on the south. Behind the latter is the Anse (bay) de la Réserve. Beyond this again, situated in succession along the shore, come the Château du Pharo, which was given to the town by the empress Eugénie, the Anse du Pharo and the Anse des Catalans. In the roads to the southwest of the port lie the islands of Ratonneau and Pomègues, united by a jetty formerly forming a quarantine port but today abandoned. Between them and the mainland is the islet of Château d'If, in which the scene of part of Alexandre Dumas' *Le Comte de Monte-Cristo* is laid.

Marseilles possesses few remains of either the Greek or the Roman periods of occupation and is poor in medieval buildings. In the Place de la Major, the old cathedral of La Major (Ste. Marie-Majeure), dating chiefly from the 12th century and built on the ruins of a temple of Diana, is poorly preserved; the chapel of St. Lazare in the left aisle is early Renaissance. Beside this church and alongside the Joliette basin is the church begun in 1852, which has taken the place of the old cathedral.

On the south side of the old harbour near Ft. St. Nicolas stands the church of St. Victor, built in the 13th century and once attached to an abbey founded about 413. With its lofty crenelated walls and square towers built of large blocks of uncemented stone, it resembles a fortress. St. Victor is built above crypts dating mainly from the 11th century but also embodying architecture of the Carolingian period and of the early centuries of the Christian era. The spire of the ancient church of Accoules, and its only relic, marks the centre of Old Marseilles. Notre-Dame du Mont Carmel, also in the old town, occupies the place of what was the citadel of the Massilians when they were besieged by Julius Caesar. The celebrated Notre-Dame-de-la-Garde, the steeple of which is surmounted by a gilded statue of the Virgin, 30 ft. in height, rises 150 ft. above the summit of the hill on which it stands.

Of the civil buildings of the city, the Prefecture, one of the finest in France, the Palais de Justice and the Exchange all date from the latter half of the 19th century. The Hôtel de Ville (1673) stands on the northern quay of the old harbour. The Palais Longchamp (1862-69) is a museum and art gallery. The museum of antiquities, established in the Château Borély (1766-78), includes a Phoenician collection (containing the remains that support the hypothesis of the Phoenician origin of Marseilles). The city also has a colonial museum and a laboratory of marine zoology. The triumphal arch of Aix, originally dedicated to the victors of the Trocadéro, was in 1830 appropriated to the conquests of the empire.

The canal de Marseille, built between 1837 and 1848, which has transformed the town and its arid surroundings by bringing to them the waters of the Durance, leaves the river opposite Pertuis. It has a length of 97 mi. (including its four main branches) of which 13 mi. are underground, and irrigates approximately 7,500 ac. After crossing the valley of the Arc, between Aix and Rognac, by the magnificent aqueduct of Roquefavour, its waters are purified in the reservoirs of Reaumur. It draws about 2,200 gal. of water per second from the Durance, supplies 2,450 h.p. to works in the vicinity of Marseilles, and insures a good water supply and efficient sanitation to the city.

Marseilles is the seat of an archbishop and a prefect. It has

tribunals of first instance and of commerce, a chamber of commerce and a board of trade arbitration. The educational institutions include a school of navigation and faculties of science, medicine and pharmacy; these two faculties form part of the university of Aix-Marseilles.

The Port, Trade and Industry.—The surface area of the Vieux-Port was doubled toward the north in 1846 by the creation of the new port of La Joliette; it was afterward extended farther north by eight wet docks. The port facilities, which were destroyed by the Germans in 1944, have been rebuilt and perfected. The new port is connected by the Rove tunnel to the Étang de Berre, which opens to the sea, and by the canal which is destined to go from Marseilles to the Rhône; the portion from Étang de Berre to the river was not completed by the late 1950s. There is an old canal from Port-de-Bouc at the mouth of the estuary to Arles, on the Rhône, but it is not deep enough to permit the passage of modern ships. A new port, Lavéra, has been built in the inner harbour of Port-de-Bouc which can receive nine tankers at once without the entry being blocked. Together with the refineries which line the banks of the Étang de Berre, Lavéra is a port annex of great importance to Marseilles. The airport of Marignane is on the south bank, 17½ mi. from the centre of the city.

When they left in 1944, the Germans destroyed the fleet. By the late 1950s it had been rebuilt to a capacity of 915,000 tons distributed between passenger and cargo ships. Many lines are based there which send ships to the eastern Mediterranean, the east coast of Africa, Australia, India, Indochina, Algeria, Tunisia, Malta, Morocco and the Antilles, as well as Great Britain and the ports on the west coast of France. In addition, many of the big foreign lines call at the port, which is mainly a transshipment and industrial port instead of, as formerly, an entrepôt.

Marseilles is the western emporium for trade with the Levant and it is the French gate of the far east. It suffers from competition with Genoa for trade with Switzerland and from lack of communication with the inland waterways of France. It was hoped that improved navigation on the Rhône and the construction of one new canal from Bouc to Arles, or to St. Louis, would make the city of Marseilles the national outlet from the rich basin in which it lies.

In order of importance, the imports are crude petroleum, grains, out-of-season fruits and vegetables, carbon, sugar, peanuts, chrome, phosphates, vegetable oils and greases, cotton, rubber, wine, copra, sulfur, coffee, Indian corn, skins and leathers, bananas, dates and dried fruits, manganese and nonferrous metals. Less important are meats, dried vegetables, cocoa, leaf tobacco, exotic woods, cork, paper and cardboard, wool, iron and steel.

The major export is petroleum. After that, successively, come construction materials, machines, chemical products, sugar, carbon, metalwork, farina, automobiles, lumber, fresh vegetables, cloth, beer, tobacco, wine, soap and vegetable oils.

The industry of Marseilles is closely connected with its imports, from which are taken most of the raw materials processed there. By the early 1960s the most important industry was based on the pact of San Remo (1920), which gave France one-fourth of Iraq's production of petroleum of which a large part is refined at Berre.

The oldest and best known industry, founded in the 15th century, is that of soap. It retains its importance despite a sharp decrease since 1935. The production of sugar has decreased similarly since 1920. Even though the oil refineries represent half the production of France, drastically reduced in the late 1950s, their production is 50% of what it was formerly. Marseilles is the largest producer of semolina in France; and is the fourth largest producer of pasta, which is made from semolina. The building materials made—quicklime, cement, plaster, bricks and tiles—are a significant part of France's total. The manufacture of glass is still a major industry. Metallurgy and smelting grew in importance after World War II and Marseilles developed a very large chemical industry (sulfuric acid, superphosphates, hydrochloric acid, refined sulfur and copper sulfate), partly owing to the needs of the vine-growing region around the city.

See also references under "Marseilles" in the Index. (J. Bd.)

MARSH, JOHN (1752–1828), English amateur musician, composer and writer on music, was born at Dorking, Surrey, and, as his father was a naval officer, he spent his youth at Greenwich and Gosport, Hants. As a musician he was largely self-taught, except for a few lessons on the violin. In 1768 he was articled to a solicitor at Romsey, Hampshire. He took part in the local musical life there as well as at Winchester and at Salisbury, then the best musical centre in southern England.

In 1783 he came into a considerable fortune, including an estate near Canterbury, where he became leader of the subscription concert orchestra. In 1787 he moved to Chichester, where he remained for the rest of his life, reorganizing and directing the subscription concerts and deputizing for the cathedral organist, and where he died in 1828.

Marsh was not only a good violinist and orchestral leader but also was a competent composer, especially of chamber and orchestral music; some of his quartets and symphonies have considerable merit. He is also of interest as a writer on music; his essay, "A Comparison of Ancient and Modern Music," which first appeared in the *Monthly Magazine* for 1796 (reprinted in *Music and Letters*, April 1955), and his *Hints to Young Composers* (Chichester, c. 1806) are both useful and interesting, as are his numerous prefaces to his published instrumental works. His entertaining and informative autobiography has survived in manuscript. (Cs. CH.)

MARSH, OTHNIEL CHARLES (1831–1899), U.S. paleontologist whose discoveries and descriptions of numerous fossils won him his scientific reputation, was born in Lockport, N.Y., on Oct. 29, 1831. He graduated from Yale college in 1860, and studied geology and mineralogy in the Sheffield Scientific school there. Becoming interested in vertebrate paleontology, he studied abroad and on his return to Yale in 1866 was appointed professor of vertebrate paleontology. He was aided by a private fortune from his uncle, George Peabody, whom he induced to establish the Peabody Museum of Natural History in the college. With this backing, he sent out numerous exploring parties to Wyoming and other western states almost annually for the next three decades.

In his publications on fossil finds he utilized the studies of such scientists as Samuel Wendell Williston, Oscar Harger, Max Schlosser and George Baur; these men were not generally permitted to publish individually on vertebrate paleontology while in Marsh's employ. A host of short papers by Marsh appeared in the *American Journal of Science*; his major published works, however, were quarto volumes on toothed birds, the Dinocerata (archaic horned mammals) and North American dinosaurs. Marsh was prominent in national scientific affairs, and was president of the National Academy of Sciences for 12 years. His contemporary in the exploration of the western fossil beds was Edward Drinker Cope (*q.v.*) of Philadelphia; they were originally friends but their rivalry over collecting sites developed into a bitter feud that somewhat clouded the reputations of both. Early government geological exploration of the west had been made by several independent surveys; they were combined in 1881 to form the United States Geological survey. Marsh was put in charge of its work in vertebrate paleontology and given liberal support.

Marsh's last years were saddened by financial reverses, loss of government support and demand that fossils collected under government auspices be sent to the National museum. He died in New Haven on March 18, 1899.

See Charles Schuchert and Clara Mae Le Vene, *O. C. Marsh, Pioneer in Paleontology* (1940). An interesting account of Marsh's fieldwork and the Marsh-Cope rivalry is given in G. T. Hellman's "Onward and Upward with Science" in *The New Yorker*, vol. xxxviii, no. 37, pp. 142–176 (Nov. 3, 1962). (A. S. RR.)

MARSH, an area of low, flat-lying, wet ground subject to daily, seasonal or perennial flooding. In popular usage the term is applied interchangeably with swamp (*q.v.*). Technically marshes have many physical features common to swamps; they differ chiefly in having vegetation composed dominantly of grasses and such grasslike plants as sedges and rushes. Characteristic marsh plants include cord and salt reed grass in salt water, saw grass and reeds

in brackish to fresh water, and Indian rice and giant cane in fresh water.

Salt- and brackish-water marshes are common along low sea-coasts, inside barrier bars and beaches, in estuaries and on deltas, and are often extensive in deserts. Maritime marshes often extend many miles inland and are variably subjected to tidal action. Fresh-water marshes are found frequently on mineral substrates of alluvial and lacustrine origin and are both numerous and extensive on upland areas with impeded drainage, particularly those, such as the most recently glaciated areas of North America, with underdeveloped drainage. Marshes were ubiquitous in the prairie of the midwestern United States, but their value as agricultural soils resulted in early drainage and cultivation. As wildlife refuges they provide a valuable economic and recreational resource.

Notable marshes in the United States are the Everglades of Florida, the tule marshes of the Sacramento and San Joaquin valleys of California and the Humboldt Salt marsh of Nevada. The vast Pripet marshes in the Soviet Union and the Pontine marshes near Rome are of particular historical interest. (M. E. B.)

MARSHAL, a title given in various countries to certain military and civil officers, often of high rank; it has evolved from the title of the *marescalci*, or masters of the horse, of the early Frankish kings. In this original sense the word survived down to the final days of the Holy Roman empire in the titular office of *Erzmarschalk* (arch-marshal), borne by the electors of Saxony.

Elsewhere the meaning of the office and title of marshal became modified. The importance of cavalry in medieval warfare led to the marshalship being associated with military command; this came to include the duties of keeping order at court and in camp, of deciding questions of chivalry and involved the assumption of judicial and executive functions. As a military leader the marshal was originally subordinate to the constable (*q.v.*). By the 12th century, however, although still nominally second to the constable, he was rapidly coming to prominence as commander of the royal forces and as a great officer of state.

The Great Marshals of England, Scotland and France.—In England there was probably a master marshal of the king's household under the first two Norman kings; the office was certainly well established in the 12th century when the marshal's duties and remuneration were noted in the *Constitutio domus regis*, an account of the staff of the royal household compiled early in Stephen's reign (1135–54). Until the mid-13th century the marshalship was hereditary in the family which derived its surname from the office. Its importance was enhanced by the marshalship of William Marshal (d. 1219) who had by marriage become earl of Pembroke. William's son Gilbert was described by Matthew Paris (*Chronica maiora*, ed. by H. R. Luard, 1872–83, vol. iii, p. 338) as the great marshal of England, who bore his baton before King Henry III and superintended the seating of guests at a feast. By the end of the 13th century the office of marshal, now passed to the Bigod earls of Norfolk, had become as important as that of constable; its holder was usually referred to as the earl marshal, but only because he was now also an earl. The title earl marshal (*q.v.*) was granted in 1386, when Richard II gave it to Thomas Mowbray, later duke of Norfolk.

In Scotland the office of marischal (from the French *maréchal*), probably introduced under David I (d. 1153), became in the 14th century hereditary in the house of Keith. In 1458 the Scottish marischal became an earl under the designation of earl-marischal. The dignity came to an end at the attainder in 1716 of George, 9th earl-marischal.

In France, however, care was always taken to prevent the office of marshal of France (*marescallus Franciae*) becoming hereditary. The office was instituted under Philip II (d. 1223), and the marshal became one of the great officers of the crown. From the time of Philip's grandson Louis IX (d. 1270) two marshals were usually appointed; Francis I (d. 1547) added a third and Henry II (d. 1559) a fourth. Henry IV, Louis XIII and Louis XIV were all responsible for further increases in the number of marshals; for a time, after the great promotions of 1703, there were 20 marshals. Between 1763 and 1788 the number varied from 15 to 16; after the Revolution it was reduced to 6 in 1791

and in 1793 the office was suppressed. In 1804 Napoleon created 18 marshals of the empire, among whom were Michel Ney, Nicolas Soult, Jean Bernadotte and Joachim Murat. At the Bourbon restoration (1815) when the title again became marshal of France, the number was reduced to 15; in 1839 it was decided that there should be no more than 6 marshals in time of peace, 12 in time of war. The title fell into abeyance after 1870 and marshals are now normally created only in time of war. Among famous earlier marshals were Turenne (created 1643) and Vauban (created 1703).

Marshals of Army and Air Force.—The word marshal in the sense of commander of an army was used as early as the 13th century in England; in 1214 King John appointed William, earl of Salisbury, *marescallus* of his forces. The modern military title of field marshal, imported from Germany by King George II in 1736, is derived from the high dignity of the Frankish *marescallus* in a roundabout way. The marshal, being responsible for order in court and camp, had to employ subordinates who soon became only nominally dependent upon him. These were the *marescalci campi* or *maréchaux de camp*. On military expeditions two or more such marshals preceded the army, to select the site of the camp and assign places in it. In peacetime they arranged the king's lodging and maintenance when he traveled. The French title *maréchal des logis*, the marshal in charge of billeting, existed from the time of Louis XIV until the Revolution, and remained in the French and Belgian armies to denote a quartermaster in cavalry regiments. A modern use of the title marshal in connection with warfare is the style air marshal, given to high-ranking officers of the British and some Commonwealth air forces. A provost marshal is an officer in charge of military police.

Marshals with Judicial Functions.—In England, from the time of Edward III (d. 1377), the marshal and the lord steward (*q.v.*) presided in the Marshalsea court, held to settle disputes to which members of the household were party. This court was abolished in 1849. There was also until 1841 a *marescallus banci regii* (marshal of the king's bench), responsible for the custody of those detained in the Marshalsea prison.

The official known as judge's marshal, usually a newly called barrister, attends each assize judge, acting as his secretary and personal assistant.

In the United States the title marshal is used to denote two types of executive legal officer. The United States marshal, appointed by the president with the consent of the senate, is the executive officer of the federal courts. One marshal is normally appointed for each district. The marshal's duties are to open and close the sessions of the district and circuit courts, serve warrants and execute the orders of the court. The temporary police sworn in to maintain order in times of disturbance, known in England as special constables, are also termed marshals in the United States. In some cities the head of the fire department is known as the fire marshal.

MARSHALL, ALFRED (1842–1924), British economist who, through the influence of his work, was one of the chief founders of the school of neoclassical economists, was born in London on July 26, 1842. Educated at Merchant Taylors' school and at St. John's college, Cambridge, in 1877 he became the first principal of University college, Bristol, but resigned in 1881 because of ill health. He was a fellow and lecturer in political economy at Balliol college, Oxford, from 1883 to 1885, when he returned to Cambridge as professor of political economy in succession to Henry Fawcett. He was a member of the royal commission on labour from 1891 to 1894 and subsequently served in several government inquiries. In 1903, after years of struggle, he succeeded in establishing an economics tripos at Cambridge, separate from the moral sciences tripos. He retired from the chair of political economy in 1908 and thenceforward devoted himself to his writings until his death at Cambridge on July 13, 1924.

Marshall's first big work, *Principles of Economics* (1890), was in many ways his most important contribution to economic literature. His next volume, *Industry and Trade*, a realistic study of industrial organization, did not appear until 1919, but in the meanwhile he had devoted much time and energy to bringing out suc-

cessive editions of his *Principles*. In 1923 he published his last volume, *Money, Credit and Commerce*. Marshall may be said to have been in the lineal descent of the great English economists—Adam Smith, Ricardo and J. S. Mill. His *Principles of Economics* was distinguished by its profound and systematic methods of analysis and by the introduction of a number of new concepts, such as elasticity of demand, consumer's surplus, quasi rent, the representative firm, etc., which played a great role in the subsequent development of economics. Writing at a time when the economic world was deeply divided on the theory of value, he succeeded, largely by introducing the element of time as a factor in analysis, in reconciling the classical cost of production principle with the marginal utility principle formulated by William Jevons (*q.v.*) and the Austrian school. He did much to rescue economics from rigid dogmatism by insisting that economic reasoning and laws were not themselves a body of concrete truth but an engine for the discovery of concrete truth. (C. W. G.; X.)

MARSHALL, GEORGE CATLETT (1880–1959), U.S. army officer who directed the organization and training of U.S. land and air forces during World War II, later served as secretary of state and of defense, was author of the Marshall plan for European recovery and was winner of the Nobel peace prize (1953). He was born at Uniontown, Pa., on Dec. 31, 1880, and graduated from the Virginia Military institute, Lexington, in 1901. Commissioned as a second lieutenant in Feb. 1902, with date of rank from Feb. 1901, his first service was in the Philippines (1902–03). He was advanced through the grades to general of the army in Dec. 1944. As a five-star general he was still on active duty and the highest ranking officer of the army at the time of his death.

In World War I he served as chief of operations of the 1st army and chief of staff of the 8th army corps. He drafted plans for the St. Mihiel operation and later was assigned the problem of transferring more than 500,000 men and 2,700 guns to the Argonne front for the Meuse-Argonne battle.

After World War I, he was an aide to Gen. John J. Pershing from

1919 to 1924 and served with the 15th infantry regiment in Tientsin, China (1924–27). As assistant commandant in charge of instruction (1927–32) at the infantry school, Ft. Benning, he strongly influenced army doctrine and such later wartime leaders as Bradley, Collins, Ridgway, Stilwell, Bedell Smith, Hodges and Bolté. He was sworn in as chief of staff of the army on Sept. 1, 1939, the day World War II began with the invasion of Poland by German troops. For the next six years, Marshall directed the raising of new divisions, training of troops, development of new weapons and equipment, and selection of top commanders. He was chief of staff of the army at the time of Pearl Harbor. As

BROWN BROTHERS
GEORGE C. MARSHALL IN 1947 AS
SECRETARY OF STATE

an adviser to Pres. Franklin D. Roosevelt on strategy, he attended the conferences at Casablanca, Quebec, Tehran, Yalta and Potsdam.

Marshall resigned as chief of staff Nov. 21, 1945. A few days later he was appointed special representative of Pres. Harry S. Truman to China with rank of ambassador. He was unsuccessful in his efforts to mediate the Chinese civil war.

Appointed secretary of state by President Truman on Jan. 21, 1947, he headed—the next two years—U.S. delegations to international conferences at Moscow, Rio de Janeiro, Bogotá, Paris, London and New York. On June 5, 1947, at Harvard university he proposed a European Recovery program which, known as the Marshall plan (*q.v.*), was enacted into law in April 1948. The Greek and Turkish aid programs, recognition of Israel and the initial discussions of the North Atlantic Treaty organization (NATO) agreements came during his secretaryship. He resigned on Jan. 21,

1949. In the course of the year he was named chairman of the American Battle Monuments commission and president of the American Red Cross.

Marshall was secretary of defense under Truman from Sept. 21, 1950, to Sept. 12, 1951. In this post he helped implement the NATO agreements. He pressed vigorously for increases in man power and production of matériel to strengthen U.S. forces in Korea, and urged the establishment of a universal military training program.

He represented Pres. Dwight D. Eisenhower at the coronation of Elizabeth II in 1953. Later in the same year he was awarded the Nobel peace prize in recognition of his contributions to the economic rehabilitation of Europe after World War II and his efforts to promote international peace and understanding. He died in Washington, D.C., Oct. 16, 1959, and was buried in Arlington National cemetery.

MARSHALL, JOHN (1755–1835), fourth chief justice of the United States whose constitutional decisions gave shape and definition to the structure of the federal government, was born on Sept. 24, 1755, near a settlement then called Germantown (now Midland), Va., the eldest of 15 children of Thomas Marshall (1730–1802) and Mary Keith Marshall. His childhood and youth were spent in the near-frontier region which in 1759 became Fauquier county, first in the forested area of southern Fauquier in which he had been born, later on in the more extensive properties his father acquired in the Blue Ridge mountain area north and west of Warrenton. His education appears to have been largely the product of his parents' efforts, supplemented only by the instruction afforded by a visiting clergyman who lived with the family for about a year, and by a few months of slightly more formal training at an academy in Westmoreland county. Thomas and Mary Marshall, however, had more learning and wider experience to transmit to their children than was common among the farmers and hunters of the back country of northern Virginia. Mary Keith Marshall was the daughter of a college-trained Scottish clergyman who had migrated to Virginia. Thomas Marshall brought to the family circle a continually broadening experience. A friend of George Washington, he had been his assistant in surveying the extensive estates of Lord Fairfax. Soon after Fauquier county was established he was elected its representative in Virginia's house of burgesses. His career of officeholding next included service as sheriff of Fauquier county, a return to the house of burgesses, appointment as clerk of Dunmore county, followed once again by service in the house of burgesses. This was the period when the differences between the upland counties and the tidewater aristocracy grew sharp and were paralleled by an increasing sentiment for colonial autonomy and finally for independence among the back-country residents whom Thomas Marshall represented.

Early Career.—When political debate with England was followed by armed clashes in 1775, John Marshall, as lieutenant, joined his father in a Virginia regiment of minutemen and participated in the first fighting in that colony. Joining the Continental army in 1776, he served under Washington for three years in New Jersey, New York and Pennsylvania, including in this service the harsh winter of 1777–78 at Valley Forge. When the term of service of his Virginia troops expired in 1779, Marshall returned to Virginia and thereafter saw little active service prior to his discharge in 1781.

Marshall's career in law dates from 1780. His only formal training was a brief course of lectures given by George Wythe which he attended at William and Mary college early in that year. Licensed to practise in Aug. 1780, he returned to Fauquier county and was elected to the Virginia house of delegates in 1782 and 1784. Attending the sessions of the legislature in the capitol at Richmond, he established there both a law practice and a home after marriage to Miss Mary Ambler in Jan. 1783.

For the next 15 years Marshall's career was marked by increasing stature at the brilliant bar of Virginia. He had not, in 1787,

achieved a public position which would have sent him as a delegate to the Constitutional Convention in Philadelphia, but he was an active, if junior, proponent of the constitution in the closely contested fight for ratification. Virginia was then the largest and most populous of the states. Its ratification was not only essential to the success of the proposed constitution but was also among the most doubtful. Marshall was elected to the legislature which took the first step toward ratification by issuing a call for a convention to consider ratifying; he was also elected a delegate to the convention. On the floor of that convention the contest on behalf of the constitution was led by men senior to Marshall—James Madison, Edmund Randolph, Edmund Pendleton and Wilson Cary Nicholas; Patrick Henry and George Mason led the opposition. Marshall made one address in reply to a general attack by Henry. His principal effort on the floor was, perhaps prophetically, a defense of the judiciary article. It can only be assumed that his acknowledged popularity was employed with at least equal effectiveness off the floor to gain or hold the narrow margin by which Virginia's ratification was won.

With the new government under the constitution installed, President Washington offered Marshall appointment as United States attorney for Virginia. Marshall declined. In 1789, however, he sought and obtained a further term in Virginia's house of delegates as a supporter of the national government. As party lines emerged and became defined in the 1790s, Marshall became recognized as one of the leaders of the Federalist party (*q.v.*) in Virginia. In 1795, Washington tendered him an appointment as attorney general. This, too, was declined, but Marshall returned to the state legislature as a Federalist leader. His first federal service came when Pres. John Adams appointed him member of a commission, with Elbridge Gerry and Charles C. Pinckney, to seek improved relations with the government of the French republic. The mission was unsuccessful. But when its reports were published disclosing the approach of intermediaries, the shadowy figures of "X, Y and Z," who informed the commissioners that they would not be received by the French government unless they first paid large bribes, and the rebuff of these advances in a memorial which Marshall had prepared, Marshall became a popular figure and the conduct of his mission was applauded by one of the earliest American patriotic slogans, "Millions for defense, but not one cent for tribute."

Returned from France, Marshall declined appointment to the supreme court to succeed Justice James Wilson but was persuaded by Washington to run for congress. He was elected in 1799 as a Federalist from the Richmond district, though not until he had expressed opposition to the unpopular alien and sedition laws which the Adams administration had sponsored (*see UNITED STATES [OF AMERICA]: History: Rise of the American Nation, 1783-1850*). His service in the house was brief. His chief accomplishment there appears to have been the effective defense of the president against a Republican attack for having honoured a British request under the extradition treaty for the surrender of a seaman charged with murder on a British warship on the high seas. In May 1800, President Adams requested the resignation of his secretary of war and offered the post to Marshall. Marshall declined. The president next dismissed his secretary of state and tendered the vacant place in his cabinet to Marshall. In an administration harassed by dissension and with uncertain prospects in the forthcoming election, the appeal of the invitation must have been addressed principally to Marshall's loyalty. After some hesitation he accepted and almost immediately became the effective head of government when the president retired to his home in

Massachusetts for a stay of a few months. In the autumn of 1800, Chief Justice Oliver Ellsworth resigned owing to ill health. Adams, defeated in the election of November, tendered reappointment to John Jay, the first chief justice. Jay declined. The president then turned to his secretary of state and in Jan. 1801, sent to the senate the nomination of John Marshall to be chief justice of the United States. The last Federalist senate confirmed the nomination on Jan. 27, 1801. On Feb. 4, Marshall accepted the appointment but, at the president's request, continued to act as secretary of state for the last month of the Adams administration.

Chief Justice of the United States.—It fell to Marshall, and to the supreme court under and beginning with Marshall, to set forth the main structural lines of the government. Whether the constitution had created a federation or a nation was not a matter on which agreement could have been won at the beginning of the 19th century. Though judicial decisions could not alone dispel differences of opinion, they could create a body of coherent, authoritative and disinterested doctrine around which opinion could mass and become effective. To the task of creating such a core of agreement Marshall brought qualities which were admirably adapted for its accomplishment. His own mind had apparently a clear and well organized concept of the effective government which he believed was needed and was provided by the constitution. He wrote with a lucidity, a persuasiveness and a vigour which gave to his judicial opinions a quality of reasoned inevitability which more than offset what they sometimes lacked in precision of analysis. The 35 years of his magistracy gave opportunity for the development of a unified body of constitutional doctrine. It was the first aspect of Marshall's accomplishment that he and the court which he headed did not permit this opportunity to pass unrecognized.

Prior to Marshall's appointment, it had been the custom of the supreme court, as it was in England, that each justice deliver an opinion in each significant case. This method may be effective where a court is dealing with an organized and existing body of law. With a new court and a largely unexplored body of law, it created an impression of tentativeness, if not of contradiction, which lent authority neither to the court nor to the law it expounded. With Marshall's appointment, and presumably at Marshall's instance, this practice changed. Thereafter, for some years, it became the general rule that there was only a single opinion from the supreme court, and that delivered by the chief justice. This change of practice alone would have contributed to making the court a more effective institution. And when the opinions were cast in the mold of Marshall's clear and compelling statement, growth of the court's authority came as a result which might have been, and presumably was, anticipated.

Marbury v. Madison (1803) was the first of Marshall's great cases and the case which established for the court its power to state and expound constitutional law in disregarding federal statutes which it found in conflict with the constitution. President Adams had appointed a number of justices of the peace for the District of Columbia shortly before his term expired. Their commissions had been signed and the seal of the United States affixed in the office of the secretary of state, but some of them, including that of William Marbury, remained undelivered. President Jefferson is believed to have ordered that some of them not be delivered. After unsuccessful application at the department of state, Marbury instituted suit in the supreme court against James Madison, the new secretary. Though the matter was not beyond question, the court found that congress had by statute authorized that such suits be started in the supreme court rather than in a lower court. But the supreme court, speaking through Marshall, held that art. iii of the constitution did not permit this, and that the court could not follow a statute which was in conflict with the constitution. It thereby confirmed for itself its most controversial power, the function of judicial review, of finding and expounding the law of the constitution.

Marshall's emphasis was put on the assertion that if the constitution was to be a lasting and controlling document, judges who were sworn to uphold it could not follow a law which conflicted with it. As Chief Justice John Bannister Gibson of the supreme court of Pennsylvania later pointed out, the problem was not so

THE BETTMANN ARCHIVE
PORTRAIT OF JOHN MARSHALL
PAINTED BY CEPHAS THOMPSON, 1810

much whether the court should follow laws which conflicted with the constitution as it was who—court or congress—should determine whether the conflict existed, a matter often as uncertain as it was in *Marbury's* case. This great power of determining whether there was conflict between a law and the constitution was not explicitly given to the court. As early as 1796 it had held ineffective a state law which it found in conflict with federal law, and in the same year had considered a constitutional challenge to a federal tax, but had left without specific decision its power to disregard a federal statute. Marshall's was the first decision which asserted and acted upon this authority. Though the court's action has been questioned, and even termed usurpation, history lends strong support to Marshall's action. British judges had passed upon the question whether the acts of colonial legislature were consistent with their charters, so the function was not an unfamiliar one. There was some history of state courts having done the same with respect to state laws and state constitutions. Most of the leaders of the Constitutional Convention and many of those in state ratifying conventions appear to have contemplated judicial review and to have assumed that it would be exercised. And the terms of the Judiciary act passed by the first congress in 1789 appear equally clearly to have contemplated that this function would be carried out by judges subject to ultimate review by the supreme court.

Once the power of judicial review had been established, Marshall and the court followed with decisions which assured that it would be exercised, and the whole body of federal law determined, in a unified judicial system with the supreme court at its head. In *Martin v. Hunter's Lessee* (1816) the court overruled the court of appeals of Virginia, which had held that the state courts were not subject to review by the supreme court, even in cases where federal questions were involved. Marshall did not participate in this case because the specific point at issue was ownership of the Fairfax estate in which he had a large interest. But in *Cohens v. Virginia* (1821), Marshall followed the same reasoning and went a step further in holding that even criminal cases in the state courts, in which a state itself was a party, were subject to review by the supreme court if a question under federal law arose in the case. This decision provoked vigorous opposition by Judge Spencer Roane of Virginia, but it is clear that a unified federal system could hardly have been maintained had Marshall's decision been otherwise. And in *United States v. Peters* (1809), Marshall had already closed another possible gap in federal authority by holding that once the federal courts had acted, not even a state legislature could interpose effective authority to nullify or set aside its order or judgment.

After asserting the authority of federal judges to interpret and apply the constitution, Marshall's most important decision in the exercise of this function was in *McCulloch v. Maryland* (1819) in which he upheld the authority of congress to create the Bank of the United States. Once again he was dealing with a power not explicitly given, for the constitution did not in so many words empower congress to create a corporation or establish a bank. But Marshall found that if congress determined that a corporation exercising banking powers would be a useful and appropriate means of accomplishing its purpose within the granted powers of regulating commerce, borrowing money, collecting taxes, paying and supporting troops, and the like, its action was authorized by the constitution. In writing "[W]e must never forget that it is a constitution we are expounding . . . Let the end be legitimate, let it be within the scope of the constitution, and all means which are appropriate, which are plainly adapted to that end, which are not prohibited, but consist with the letter and spirit of the constitution, are constitutional," Marshall set a standard of judgment of congressional action which would validate the expanding federal legislation of later years. *McCulloch v. Maryland* well illustrates that judicial review may have an affirmative aspect as well as a negative. It may accord an authoritative legitimacy to contested government action no less significant than its restraint of prohibited or unauthorized action.

The constitution had been called into being as much by the need for restricting state legislation hostile to the commerce of other states as by any other single factor. It granted to congress

the power to "regulate commerce . . . among the several states." It left open the question whether, or to what extent, state regulatory laws could be applied to interstate commerce. In order to encourage the development of the steamboat, New York had granted to Fulton and Livingston, and their licensees, a long-term monopoly of steam navigation on the waters of the state. In *Gibbons v. Ogden* (1824), the question was whether this New York statute could operate to exclude vessels propelled by steam and coming from another state. In dealing with the problem, Marshall first set forth the great scope of the power granted to congress by the commerce clause. There remained the dilemma whether this excluded state action in the field when congress had not acted. Marshall saw that many state laws primarily of local concern would be ineffective if they could not be applied to persons and goods from other states. At the same time many others could operate to evoke hostility and reprisals from other states, as indeed New York's steamboat monopoly was doing. In *Gibbons v. Ogden*, after an extensive survey of the problem which left it unanswered, Marshall resolved that particular case by invoking federal authority in the form of a federal coasting licence possessed by the New Jersey vessel to override New York's statutory monopoly. Yet in *Wilson v. Black Bird Creek Marsh company* (1829), Marshall held in a brief and inexplicit opinion that a similar coasting licence could not justify destruction of a dam across a navigable stream which Delaware had authorized in order to drain a marsh. These apparently conflicting decisions showed not contradiction or indecision but rather a recognition that the problem was a complex one incapable of solution by any simple rule or formula. It remained for Marshall's successors to recognize explicitly what Marshall's decisions had foreshadowed, that such problems could be dealt with only on the particularized basis of appraising the competing interests of the state and of a nationally open market in the circumstances of each case. When Maryland, however, imposed a special tax upon importers, thereby creating a hostile discrimination against foreign goods in the local market, Marshall had little difficulty in deciding, in *Brown v. Maryland* (1827), that this taxing statute was unconstitutional. Though the result of that decision was not questioned thereafter, Marshall's opinion in *Brown v. Maryland* was not among his happiest. Instead of basing the decision upon the fact that the tax was discriminatory, Marshall held instead that for a time imports must be completely tax exempt. He suggested that this exemption existed during the time they remained in the original package and before the first sale. The opinion, rather than the result of the decision, posed for successor judges many difficult problems in enforcing general non-discriminatory state taxes insofar as they relate to imported goods.

Marshall's decisions dealing with the authority and organization of the federal government and with federal-state relationships created an organized structure upon which his successors have for the most part built and elaborated. His decisions dealing with the specific restraints upon government, chiefly involving the provision of art. i of the constitution that "No State shall . . . pass any . . . Law impairing the Obligation of Contracts," proved less enduring in establishing the working limits within which state governments must operate. Though *Fletcher v. Peck* (1810)—holding that a state could not legislatively revoke an executed sale of land which had subsequently been acquired by innocent purchasers—presumably remains effective (either by virtue of the 14th amendment or the contract clause), other decisions by Marshall under the contract clause have been modified. In *New Jersey v. Wilson* (1812), Marshall held that a legislative grant of tax exemption to land occupied by Indians remained effective and could not be denied by the state even after the land had been purchased by others. The construction which interpreted the grant in such sweeping terms was presumably qualified by Marshall himself in *Providence Bank v. Billings* (1830). The decision in *Trustees of Dartmouth College v. Woodward* (1819), that a grant of a corporate charter constituted a contract which was inviolate against subsequent amendment, was effectively lessened in scope both by more restrictive construction of such charters and by the subsequently developing practice of state legislatures in specifically reserving the power to amend. The decisions in *Sturges v. Crown-*

inshield (1819) and in *McMillan v. McNeill* (1819), holding that state laws could not grant a discharge to insolvent debtors, were modified by *Ogden v. Saunders* (1827) with respect to debts incurred after the passage of the state law. This decision was one of the few cases decided while Marshall was on the supreme court in which the majority did not agree with him, and in which he dissented. If it was true that Marshall's decisions attempting to mark out the scope of the constitution's specific prohibitions on government have been among his less enduring ones, the same has been no less true of his successors. It is in this area that judicial review has evoked its most vigorous critics.

For the first 30 years of his service as chief justice, Marshall's life was singularly happy. In the autumn of 1831, at the age of 76, he underwent the rigours of surgery for the removal of kidney stones and appeared to make a rapid and complete recovery. But the death of his wife on Christmas of that year was a blow from which his spirits did not so readily recover. In 1835 his health declined rapidly and on July 6 of that year he died in Philadelphia. He lies buried in Richmond, where he had maintained a home for many years. It was said of him by Justice Holmes, "When we celebrate Marshall we celebrate at the same time and indivisibly the inevitable fact that the oneness of the nation and the supremacy of the national Constitution were declared to govern the dealings of man with man by the judgments and decrees of the most august of courts." It is his lasting memorial that when the phrase "the great chief justice" is used, the reference is unmistakably to John Marshall.

(Et. J. B.)

MARSHALL, LOUIS (1856-1929), U.S. lawyer and Jewish community leader best known for his efforts to extend religious, cultural and political freedom to all racial, religious and linguistic minorities, was born in Syracuse, N.Y., on Dec. 14, 1856. He achieved eminence as an appellate lawyer, and made many important contributions to legal and constitutional reforms. At the Paris peace conference of 1919 he successfully advocated treaties signed by a number of eastern European countries intended to protect minority rights (see MINORITIES). His opposition to Henry Ford's *Dearborn Independent*, and particularly to its circulation of the forged "Protocols of the Elders of Zion," helped bring about the discontinuance of this publication. He helped develop many religious and philanthropic Jewish organizations of national and international scope. He died at Zürich, Switz., on Sept. 11, 1929. His writings are collected in *Louis Marshall: Champion of Liberty*, edited by Charles Reznikoff (1957). (A. EN.)

MARSHALL, STEPHEN (c. 1594-1655), was a leader among the Presbyterians in England in the mid-17th century. He was born at Godmanchester, Huntingdonshire, and educated at Emmanuel college, Cambridge. Some time before 1629 he became vicar of Finchamfield, Essex, where he continued until 1651, when, on grounds of dissatisfaction with "the parochial way," he became town preacher at Ipswich. Although he thus held no official position in London, beyond a lectureship at St. Margaret's, Westminster, from 1640 onward, Marshall's prominence in religious affairs was recognized and at his death he was buried in Westminster abbey (thence to be exhumed at the Restoration). In 1641 he was one of five writers (the other four being E. Calamy, T. Young, M. Newcomen and W. Spurstow) who, over the nom de plume of their combined initials, Smectymnus, made a noted attack on episcopacy and liturgy conceived as of divine right and

unalterable. In 1643 Marshall became a member of the Westminster assembly. When in 1646 parliament ordered Presbyterianism to be established in England, he was among those nominated to serve as elder in his local classis. He held the Presbyterian polity within each congregation to be of divine right, but was not opposed to a measure of congregational autonomy and was willing for discussion with Independents. Less a man of learning or originality than a *vulgarisateur*, he was a powerful preacher; of more than 30 pieces from his pen, many were sermons preached before parliament. He died in London on Nov. 19, 1655.

(G. F. N.)

MARSHALL, THOMAS RILEY (1854-1925), 28th vice-president of the United States, was born in North Manchester, Ind., on March 14, 1854. He attended the public schools of that community and graduated from Wabash college, Crawfordsville, Ind. He studied law in the office of Judge Walter Olds, in Fort Wayne, and was admitted to the bar on his 21st birthday. Between 1875 and 1909 he practised law in Columbia City, Ind. Marshall gained a state-wide reputation as a forceful and entertaining speaker and was elected governor in 1908. He was nominated for vice-president on the Democratic ticket at Baltimore in 1912, following the stormy proceedings in which Woodrow Wilson was finally nominated for president. Marshall was elected that year and re-elected in 1916, the first vice-president to succeed himself in almost a century.

Marshall presided over the senate with fairness, tact and poise. His personal influence on legislation was a powerful aid to the administration. For almost two years following the outbreak of World War I he advocated strict neutrality, a stand he later regretted. Following the war, he proved a strong advocate of the League of Nations, and opposed women's suffrage. He won friends with his kindness, tolerance and whimsical humour. During a tedious debate in the senate on the needs of the country he was heard to comment: "What this country needs is a really good five-cent cigar." His homespun philosophy and love of fun are preserved in his book *Recollections of Thomas R. Marshall: a Hoosier Salad* (1925). He served on the U.S. Coal commission in 1922 and died in Washington, D.C., on June 1, 1925.

See C. M. Thomas, *Thomas Riley Marshall, a Hoosier Statesman* (1939). (H. F. Ty.)

MARSHALL, THURGOOD (1908-), U.S. Supreme Court justice, was the attorney who successfully argued before the U.S. Supreme Court in 1954 that racial segregation in public schools was unconstitutional in the historic *Brown v. Board of Education* case. Marshall was born July 2, 1908, in Baltimore, Md., the great-grandson of a slave. He received an A.B. *cum laude* from Lincoln University, Pa., in 1930 and three years later was graduated from Howard University law school, Washington, D.C., *magna cum laude* and first in his class. In 1938 he became special counsel for the National Association for the Advancement of Colored People (NAACP) and, two years later, chief of its legal staff. During the 23 years he served the NAACP he won 29 out of the 32 cases he argued before the U.S. Supreme Court.

On May 17, 1954, the U.S. Supreme Court ruled that "separate but equal" educational facilities failed to provide equal protection and due process of law, and was unconstitutional. The decision overruled the *Plessy v. Ferguson* decision of 1896.

Marshall was nominated to the U.S. Court of Appeals for the Second Circuit in September 1961 by Pres. John F. Kennedy. Later he was given a recess appointment and renominated in January 1962. Opposition from southern senators delayed his con-

THOMAS MARSHALL

firmation for several months until the nomination was forced to a floor vote in which he was approved. Pres. Lyndon B. Johnson named Marshall U.S. solicitor general in July 1965, the first Negro to hold that position. In June 1967 President Johnson nominated Marshall to be the first Negro member of the Supreme Court.

MARSHALL, a city of eastern Texas, U.S., seat of Harrison county, is 38 mi. W. of Shreveport, La. It is a historic community, settled in 1839, named for U.S. Chief Justice John Marshall, incorporated in 1843 and chartered in 1848. It adopted the council-manager form of municipal government in 1909. Situated on the Texas and Pacific railway, Marshall is the centre of a farming area (cotton, sweet potatoes, peas, cattle) with considerable oil production. It has large railroad repair shops, and manufactures include steel products, bricks and foundry items.

Marshall is the seat of the East Texas Baptist college (chartered 1917) and two colleges established for Negroes, Bishop college (1881) and Wiley college (1873). Considerable tourist trade is derived from nearby Caddo lake, a popular vacation spot. For comparative population figures see table in TEXAS: Population. (N. McG.)

MARSHALL ISLANDS are the easternmost group of islands in Micronesia (*q.v.*) and the eastern district of the United States Trust Territory of the Pacific Islands. Two of the atolls, Kwajalein and Eniwetok, were the scenes of heavy fighting during World War II. Later Bikini and Eniwetok became centres for atomic bomb experiments, outside the jurisdiction of the Trust administration. (The islanders were transferred to other atolls by the U.S. navy, and in 1957 were paid \$500,000 in reparations.) The administrative centre of the Marshall Islands district is located on Majuro. The islands extend roughly from latitude 3° to 15° N. and from longitude 161° to 172° E. Their land area is 61 sq.mi., and the lagoon area is about 4,500 sq.mi. A reef-enclosed lagoon 70 mi. long with an area of 840 sq.mi. makes Kwajalein the largest atoll in the world. The population increase (from 10,553 in 1948 to 17,363 in 1963) in the face of limited natural resources threatened the economy after mid-century.

The Marshall Islands are arranged in two parallel rows: the Ratak chain to the east and the Ralik chain to the west. These islands are coral caps on great dome volcanoes which rise 18,000 ft. from the floor of the ocean. Cores have been drilled on Eniwetok to depths of 4,222 and 4,610 ft. through coral limestone before reaching the volcanic stone base of olivine basalt. The fossil evidence so obtained indicates that the islands have been sinking slowly since Eocene times. Drills and soundings made on other islands indicate a similar origin. The dome volcanoes have formed in two rows which correspond to lines of weakness in the ocean floor. Most of the Marshall Islands are true atolls with central lagoons enclosed by coral reefs on which storms have piled small islets. Since these islets seldom rise more than 20 ft. above high tide they are easily flooded during storms, typhoons and tidal waves. A few of the islands have undergone recent uplift which has left shallow lagoons or none at all.

Although various Spanish expeditions of the 16th century passed through the Marshall Islands, the lack of wealth discouraged further exploration and mapping. Captain Marshall partially explored them in 1788 but much of the mapping was done by Russian expeditions under Adam Ivan Krusenstern in 1803 and Otto von Kotzebue in 1815 and 1823. Spain's claims to the islands were recognized in 1886. After the Spanish-American War, Spain sold the Marshalls to Germany. Japan seized the islands in 1914 and administered them as a mandate from the League of Nations. The United States administration was made a formal United Nations trusteeship, July 18, 1947. See also PACIFIC ISLANDS. (C. A. MR.)

MARSHALL PLAN, also known as the European Recovery Program (ERP), a program of U.S. economic aid to Europe in the post-World War II period. On June 5, 1947, in an address at Harvard university, George C. Marshall, the U.S. secretary of State, advanced the idea of a program of European economic self-help supported by U.S. assistance. On the basis of a unified plan for western European economic reconstruction presented by a committee representing various European powers, the U.S. con-

gress in Dec. 1947 authorized establishment of ERP. It was administered by the U.S. Economic Cooperation Administration (ECA) and the Organization for European Economic Cooperation (O.E.E.C.), the European co-ordinating body.

See FOREIGN AID PROGRAMS; see also references under "Marshall Plan" in the index.

MARSHALLTOWN, a city located near the geographical centre of Iowa U.S., the seat of Marshall county, is on the Iowa river about 50 mi. N.E. of Des Moines. Large wholesale businesses and diversified industries have been developed, including the manufacture of furnaces, pressure valves, governors, die castings and canned goods. It was named for Marshall, Mich., in 1851 by the first settler, Henry Anson. Marshalltown became the county seat in 1859 and was incorporated as a city in 1863. When hospitalization of Civil War veterans became a matter of state concern, the town donated 128 ac. which became the site of the Iowa Soldiers' home, now a state residence for disabled and aging Iowa veterans of all wars. Its community school district supports a junior college (1927). For comparative population figures see table in Iowa: Population. (J. F. Wa.)

MARSH MALLOW (*Althaea officinalis*), a Eurasian and north African plant of the mallow family (Malvaceae; *q.v.*). Allied to the hollyhock (*q.v.*), found in Great Britain and sparingly naturalized in the eastern U.S., it grows in marshes, especially near the sea. Sweetmeats and the original marshmallow paste were formerly made from the mucilaginous root, and both roots and leaves have been used in medicine as demulcents.

In the United States marshmallow is a confection of sugar, corn sirup, albumen and gelatin (see also CONFECTIONERY MANUFACTURE).

MARSHMAN, JOSHUA (1768–1837), English Baptist missionary and orientalist, was born on April 20, 1768, at Westbury Leigh, in Wiltshire. In 1799 he was sent by the Baptist Missionary society to join its mission at Serampur, India. There he translated the Bible into various dialects and, aided by his son, established newspapers, the first in an oriental language, and founded Serampur college. He translated into Chinese the book of Genesis, the Gospels, Romans and Corinthians; in 1809 he published *The Works of Confucius* with an English translation and in 1814 his *Clavis Sinica*, a Chinese grammar. He died at Serampur on Dec. 5, 1837. His son, J. C. Marshman (1794–1877), wrote a history of India and a life of his father (1859).

MARSH MARIGOLD, the name for several small herbs of the genus *Caltha*, plants of the buttercup family (Ranunculaceae). The common species (*C. palustris*), the "winking Mary-buds" of Shakespeare (*Cymbeline*, act ii, scene 3), are found in wet places on both sides of the Atlantic. In the U.S. it is usually called cowslip, and is often known as kingcup or May blob in Great Britain. The stem is thick and hollow; the leaves are shining and kidney-shaped; and the flowers, which bloom in spring or summer, have five yellow sepals. The early shoots and leaves have been used like spinach, and the flower buds preserved in salted vinegar form a substitute for capers. A double-flowered variety is often cultivated and is occasionally found wild. *C. natans*, a large species with white or pink flowers, occurs in ponds and muddy banks from Minnesota northward to Alaska. *C. leptosepala*, with white or bluish, usually solitary flowers, native to the Rocky mountain region from Alaska to New Mexico, is an excellent potherb. See RANUNCULACEAE.

MARSI, an ancient people of Italy, whose chief centre was Marruvium (San Benedetto de' Marsi) on the eastern shore of Lake Fucinus (now drained) in the modern province of L'Aquila. They were racially and politically connected with the Vestini, Paeligni and Marrucini (*qq.v.*) and became allies of Rome in 304 B.C. A short-lived revolt two years later recorded by Livy (x, 3) is improbable. They remained faithful down to the Social War (or "war of the allies"), their contingent being regarded as the flower of the Italian forces. In this war (91 onward), which became known as the Marsic War because of the prominence of the Marsian rebels, they fought bravely under their leader Q. Pompaedius Silo, though they were frequently defeated, the result of the war was the enfranchisement of the allies.

aid of the infantry, which had rallied and thus completed a remarkable victory.

See Austin Woolrych, *Battles of the English Civil War* (1961).
(M. P. A.)

MARSUPIAL, any of the mammals of the order Marsupialia, in which the young, born in a tiny and immature state, are usually kept for some time after birth in a pouch (marsupium) on the lower belly of the female. Among the order the best known are the strictly Australian forms, including the kangaroos, dasyures, wombats, koalas, bandicoots and phalangers; only two groups of American marsupials survive at the present time, the opossums and caenolestids, of which several different kinds inhabit Central and South America and only one, an opossum, ranges as far north as south-central North America.

GENERAL FEATURES

Typical Mammalian Characteristics.—Marsupials share with other mammals the presence of hair and the suckling of young by mammary glands. With minor differences the various systems of the body, such as the muscular and skeletal systems, are those of the placental mammals generally. The brain, however, is not so advanced as that of the placentals. (See MAMMAL; BRAIN.)

Distinctive Characteristics.—The most extraordinary features of the Marsupialia are the specializations associated with the reproductive system. In some marsupials the pouch is vestigial, being represented only by slight lateral folds, and in others it is entirely absent. There may be 2 nipples or as many as 27. Epipubic or marsupial bones, which are attached to the front end of the pelvis, are present in both sexes and are therefore not related to the support of the female's pouch. In some marsupials, like the extinct borhyaenids of South America and the marsupial "wolf" (*Thylacinus*) of Tasmania, the epipubic bones are reduced to vestiges or lost.

The female reproductive organs of marsupials differ markedly from those of placental mammals. Most marsupials have a contorted vaginal canal with one median and two lateral passages, the median one being formed from a coalescence of parts of the two laterals. In placental mammals, on the other hand, no trace of the three-way vaginal canal is evident, but the lower parts of the right and left oviducts tend to unite in a single median uterus. The marsupials specialize in an early and brief gestation, the developing embryo deriving its food chiefly from its own yolk-sack. The immature young is then born and completes its development while attached to a teat in the pouch. In the bandicoots (*Perameles*), however, an allantoic placenta (*q.v.*) forms

an intimate relationship with the uterine wall, essentially like that in the placental mammals. On the other hand, in the "tiger cats" (*Dasyurus*) only the initial stages of allantoic placenta formation can be detected.

BIRTH AND DEVELOPMENT

The cycle of reproduction differs somewhat in different marsupials. The common American or Virginian opossum (*Didelphis marsupialis*) evidently has one of the most primitive cycles, which will serve for the following discussion. During the first 5½ days the embryos form very slowly, but from that time until their birth the rate of development is remarkably fast. The gestation period is about 13 days.

The mother thoroughly cleans the pouch before parturition.

FIG. 2.—SIZE COMPARISON OF A
HONEYBEE AND A NEWBORN OPOSSUM
(DIDELPHIS)

The young, about the size of honeybees, are released from the vagina; they appear as small objects within reach, which usually the mother's fur. They are naked, blind and rather grotesque in appearance. The forelimbs, however, are large and tipped with claws; the hind legs are hardly more than embryonic buds. Immediately after birth the young use their forelimbs in a swimminglike motion, by clinging and grasping they make their way to the mammary area within the pouch. This feat is accomplished in about 16 seconds. Only about 60% of those born ever reach and enter the pouch. The more fortunate ones attach themselves to nipples that suckle and become fastened firmly in the mouths of the young. Development and early growth then continues in the pouch.

At the age of four or five weeks the young are able to leave the pouch for short intervals. Generally they remain with the mother from 90 to 100 days, oftentimes clinging to her fur. Thereafter they are weaned and begin to look after themselves.

EVOLUTION AND RELATIONSHIPS

Geologically, marsupials were doubtfully present in Asia and are definitely not known from Africa. On the whole they are considered as primitive mammals, but for some 100,000,000 years they have shown a remarkable parallel and convergent evolution with placental mammals in habits, physiological processes and structures. This convergence is so conspicuous that some genera have been referred to as marsupial "wolves," "cats," "mice" and "shrews." One South American fossil has appropriately been called a sabre-toothed marsupial.

The oldest known marsupials have been found in the late Cretaceous strata of North America. These specimens are represented mostly by tiny isolated teeth, but parts of jaws have been found. Until recently all of these have been classified in the American opossum family, Didelphidae. William A. Clemens has observed that these early marsupials were already specialized in different directions. One genus, primarily tiny animals, *Alphadon*, holds the most promise of being correctly classified in Didelphidae. On the other hand the group of small to large rodents, represented by the genus *Pedionomys*, seem rather decidedly not didelphids. The widely known genus *Eodelphis* is almost certainly not didelphid. Among its more conspicuous differences from the Didelphidae are the single (not double) rooted reduced first lower premolar and the presence of three not two lower incisors, of which the middle incisor is greatly enlarged. It is likely that this marsupial is not ancestral to any of the known later genera. Another specimen, known as *Thaladon*, the largest known Cretaceous mammal. Its bulbous premolars and large canines are indicative of an omnivorous adaptation. It is apparently referable to another family. *Alphadon* is probably nearer than any of the other Cretaceous genera to an ideal ancestral position for the marsupials as a whole, but it seems clear that obvious there were other groups of Cretaceous marsupials yet represented in our collections of fossils.

CLASSIFICATION AND SURVEY

The order is currently classified into 6 superfamilies and 14 to 18 families depending on the authority followed. Various attempts have been made to divide the marsupials into suborders but none of these have been unanimously adopted.

Two earlier and now obsolescent classifications into suborders were based upon the number and arrangement of the front teeth and the appression or separateness of certain toes. "Protodontia" was given to those marsupials having the protodont condition of the presence of at least four upper incisors. "Diprotodontia" was applied to forms having three or fewer upper incisors and no lower canines. "Didactyla" was

given to those marsupials having entirely separate toes on the hind feet; "Syndactyla" was reserved for those forms in which the second and third toes of the hind feet are enclosed in a common envelopment of skin.

The adjectival forms of these terms are still used to describe the dentition and the character of the hind feet; the proper nouns themselves are not particularly valid as indicating phylogenetic relationships, however.

AMERICAN OPOSSUMS (DIDELPHOIDEA)

Primitive marsupial characters in the didelphoids have long been recognized by mammalogists. Some of these features in the dentition, skull, body skeleton and soft anatomy may be reasonably expected to be remarkably like those in the Mesozoic ancestors of all later marsupials. Characters in the molars indicate that the Paleocene and Eocene didelphoids and borhyaenoids are closely related, but the lack of enough fossils makes it impossible to trace the lineage of all marsupial superfamilies back to the known North American Cretaceous fossils (possibly the more direct ancestors of some of the other superfamilies existed at that time). Better knowledge of the skeletons and dentitions of Cretaceous and even Early Cenozoic fossil marsupials may even-

tually alter the present interpretation of their superfamily relationships considerably.

Opomum Family (Didelphidae).—American opossums were observed in 1500 by Vicente Yáñez Pinzón, the first explorer of South America. One of the animals was taken alive, exhibited in Granada and described by Trivigiano in 1504. Later Capt. John Smith in 1612 described the opossum concisely in the following words: "An opossum hath a head like a Swine, and a taile like a Rat, and is of the bigness of a Cat"

One of the largest didelphids is the common North American opossum (*Didelphis marsupialis*), some of which exceed one yard in total length. The colour of the fur over the body is grayish-white, or, in some individuals, nearly black, due to a heavy coat of black-tipped overhair. The rounded, beadlike black eyes stand out prominently against the white, rather wedge-shaped face.

The ears are thin and naked. The tail, white throughout most of its length, is long (up to half the total length), naked, scaly and prehensile. All the toes except the opposable inner one on the hind foot bear sharp claws. The female opossum, as in most but not all marsupials, has a fur-lined abdominal pouch, which is laterally located.

The common opossum prefers wooded areas especially near streams or other bodies of water. It is both arboreal and terrestrial, and almost exclusively nocturnal in habits. It

FIG. 5.—CENTRAL AMERICAN WATER OPOSSUM, OR YAPOK (*CHIRONECTES PANAMENSIS*)

usually moves about slowly, with an ambling gait, but at times, as when pursued by dogs, it may move with considerable alacrity. The den may be a hole in the ground or in a tree. An opossum may eat almost anything, but eggs and fruit, especially persimmons, are favourite foods.

The greatest adaptive modification is seen in the water opossum (*Chironectes*), the yapok or yapó of Central and South America. This is one of the most colourful opossums. It is about the size of the common opossum. Its most conspicuous feature is an ash gray and nearly black marbled pattern to the fur on the back; the under parts are silvery white. The fur, thick and oily, has few guard hairs. The ears are large, rounded and naked. The toes of the hind feet are much longer than in other opossums and are connected by interdigital membranes, which the yapok uses to advantage in swimming. The oily nature of the pelage, and the ability to constrict the opening of the pouch tightly, makes it possible for the female to swim and to dive without jeopardizing the young, at least in their early stages of development. Five young have been found in the pouch. The water opossum constructs terrestrial nests of leaves in secluded sites near the water. Its food consists primarily of small fish, crustaceans and aquatic insects.

One species of *Philander*—the pouched, four-eyed opossums, called cuicas or guikis—ranges from Mexico to Brazil. Its total length is slightly more than two feet. This opossum may be recognized by two relatively large and widely separated white spots over the eyes, contrasting sharply with the ashy-brown pelage of the head and back. Ventrally, the colour is cream-white or pale yellow. Cuicas are terrestrial and arboreal, feeding primarily on insects and fruit. *Philander* differs conspicuously from the next genus in having a pouch.

Metachirus species, also called four-eyed opossums or cuicas, range from Costa Rica to Brazil. They are frequently confused with *Philander* species. They are about equal in size, but in *Metachirus* the two white spots above the eyes are smaller and closer together, the dorsal coloration reddish to cinnamon brown with the face darker, and there is no abdominal pouch.

Another unusually interesting opossum is the thick-tailed opossum (*Lutreolina crassicaudata*). It may be the largest of all living opossums. It occurs only in South America, where it frequents swampy areas and water courses, but may follow streams into the highlands and semidesert areas. The ears on this stocky-limbed opossum are short and rounded, scarcely extending above

OWEN J. POE

FIG. 6.—A BORHYAENID (*LYCOPSIS*) OF THE LATE MIOCENE EPOCH IN SOUTH AMERICA

the fur. There is no pouch. The pelage is a uniform rich yellowish-brown. It is said to build rounded grass nests among the rushes in swampy areas.

A small opossum that shows some interesting adaptations is *Lestodelphis halli*, from the coast of Tierra del Fuego, the southernmost tip of South America. The adult may attain about 6 in. in length. The short head, short jaws and strong molar teeth indicate flesh-eating habits; further conspicuous dentition includes the large canines and small incisors.

A genus that still seems to be undergoing considerable evolution is *Monodelphis*, the short-tailed opossums. The several species occur only in South America. These are among the smallest known of the superfamily, with total lengths ranging from 2½ to 6 in. Evidently they live mostly on the ground and are somewhat shrewlike in habits. They eat insects and other small animals but also like bananas. The colour on the back is brownish but the under parts are pale red. Some species have as many as three dark stripes down the back. The ears are short and rounded. There is no pouch, but there are up to 27 teats, as many as are known among marsupials.

No didelphids are more abundant as individuals and certainly not as species than the murine opossums, *Marmosa*. Almost 50 species, occurring from Mexico to Argentina, are currently recognized. In size they range from less than 3 in. to more than 13 in. The dominant colours are gray, brown, cinnamon and rufous; there is always a contrast between the back and belly colours. A black ring of hair is nearly always conspicuous around the eye. The ears are variable in size and are nearly bare. There is no abdominal pouch, but up to 19 teats may be present. Murine opossums are frequently taken in habitats where there are numerous vines that afford them runways from tree to tree. They are primarily insect and fruit eaters, having a special liking for bananas.

The woolly opossum genus *Gloria* is known from two species in the Andes of Ecuador and Peru. The long woolly hair is grayish-brown. Black ocular areas cover most of the face and a narrow white stripe extends from the nose to the nape. Perhaps the most distinctive feature of these unusual opossums is the tail, which is covered with hair except on the ventral side of the tip. The total length is more than 17 in.

Equally fascinating is *Dromiciops australis*, from the brushy mountain environments of the Valdivian forests of Chile and adjacent areas in Argentina. These little woolly opossums, about 8 in. long, have most of the tail covered with hair. In contrast to *Notodelphis* the canine teeth are small. The external ear is small and covered with short hair. The pouch is lined with deep cinnamon hair, quite in contrast to the whitish belly hair. The fur on the back is dark gray.

Caluromys comprises several species of medium-sized woolly opossums in Mexico and Central and South America. The short and thick back pelage is dull yellow or rufous gray, whereas the under parts are deep or pale yellow. The pale gray face has darker circles around the eyes and a dark stripe part way down the midline. The ears are large and naked. A pouch is represented by lateral rudiments.

BORHYAENIDS (BORHYAENOIDEA)

The oldest known South American marsupials are Late Paleocene in age. At that time three Neotropical superfamilies, Didelphoidea, Borhyaenoidea and Caenolestoidea, were already in existence. Patterns of the known cheek teeth of the Paleocene and Early Eocene borhyaenoids and didelphoids indicate that these marsupials may have descended from a common ancestor no earlier than the Late Cretaceous.

Borhyaenidae.—The fossil record of the family Borhyaenidae starts in the Late Paleocene and continues into the Pliocene. No genera are known to have occurred outside South America. Borhyaenids were the flesh-eating mammals of the southern continent during nearly all the Tertiary; true carnivores did not reach that region until late in the Pliocene and Pleistocene. The family name is derived from the genus *Borhyaena*, hyenalike specimens found in the Early Miocene strata of Argentina. These carnivorous marsupials had massive skulls with thick crushing teeth.

Some genera, e.g., *Proborhyaena*, were shorter-faced and more robust.

All borhyaenids were not hyenoid, however. There were the wolflike *Prothylacynus* and *Lycopsis*, and the fox- to marten-sized *Cladosictis* and *Amphiprovierra*. The most specialized of all Middle and Late Tertiary genera was the Pliocene sabre-toothed borhyaenid *Thylacosmilus*. It was about the size of a puma and even more specialized as a stabbing mammal than most sabre-toothed cats. In all, more than 20 borhyaenid genera have been described. Those like *Prothylacynus*, *Borhyaena* and *Lycopsis* have converged so closely morphologically with the marsupial wolf of Tasmania (*Thylacynus*) that some students formerly assumed the genera were closely related. It has been revealed, however, that the borhyaenids have had a long evolutionary history in South America and that they descended from a Cretaceous didelphidlike mammal.

Necrolestidae.—One fossil with a molelike adaptation called *Necrolestes* is known from the Miocene of Patagonia. It is the only known genus referable to the Necrolestidae, a family probably basically related to the Borhyaenidae or Didelphidae.

Caroloameghiniidae.—This family, named for the Argentine fossil collector Carlos Ameghino, is known from two jaw fragments with small teeth of the bunodont type, characteristic of mammals with a mixed diet. This family is tentatively placed in the Borhyaenidae.

POUCHED SHREWS (CAENOLESTOIDEA)

The other superfamily of South American marsupials is the Caenolestidae. They too are undoubtedly descendants of a Cretaceous group, but the oldest known caenolestoids are already too specialized to reveal affinities with any of the known Mesozoic fossils. Any resemblances they have to Australian groups apparently are due to convergent evolutionary trends in certain structures.

Pouched Shrew Family (Caenolestidae).—The Caenolestidae has been recorded from Early Eocene deposits, but the genera were more numerous in the Oligocene and Miocene. These little marsupials were long known from fragmentary fossils, but in 1895 Oldfield Thomas announced that this supposedly extinct family was actually represented in the living Andean mammalian fauna of Ecuador and Bolivia by an animal resembling a small rat in size and appearance. This he called *Caenolestes*. (Actually Robert F. Toms recognized the marsupial relationships of this shrewlike mammal 35 years earlier but did not name it, consequently his work was overlooked.) These terrestrial marsupial shrews are found along boggy streams in humid forests with much undergrowth. They feed on insects and spiders. The head is elongate and with rounded, medium-sized ears. The long and gently tapering tail, thickly set with short stiff hairs, is not prehensile. The diprotodont incisor teeth are suggestive of those in some of the Australian phalangeroids, but the hind feet show no trace of the phalangeroid syndactylism of the second and third toes. Other genera with living species are *Orolestes* in Peru and *Rhyncholestes* in Chile.

Polydolopidae.—This Early Cenozoic family of small specialized marsupials are related to the Caenolestidae. Their fossil remains are abundant in the South American strata of that time. They have transversely compressed and laterally ridged premolars, with serrated crests, and rodentlike incisors. The polydolopids, probably in a large measure, occupied the ecological niches that were later taken over by rodents. The fossil record indicates, however, that the polydolopids were extinct before the rodents appeared in South America.

DASYURES AND ALLIES (DASYUROIDEA)

The Australasian dasyuroids show a remarkable similarity to the American opossums in the pattern of the teeth and in the construction of the skull. The range in size of the animals is about the same. The dasyuroids are, however, much more alert and intelligent. They also differ from opossums in being primarily terrestrial. Their progressiveness is further indicated in a longer gestation period—30–33 days in the yellow-footed dasyure (*Antechinus*

flavipes). Among the most conspicuous differences between dasyuroids and didelphoids is the number of molar teeth. The dasyuroids have four above and three below, whereas the American opossums have five above and four below. There are almost 20 genera of these insectivorous and carnivorous dasyuroids, ranging from the tiny pouched "mice" to the marsupial wolf, which is as large as a German shepherd dog. *Dasyurus quoll*, the so-called native cat, was perhaps the first dasyuroid to be encountered by white men. This animal was seen on Bare Island in Botany Bay by Capt. James Cook's party in 1770. Because of superficial resemblances to other mammals dasyuroids have been called marsupial tigers, jerboas, rats and mice.

Dasyure Family (Dasyuridae).—The largest dasyuroid, the Tasmanian devil (*Sarcophilus ursinus*), is now restricted in its distribution to Tasmania, although in prehistoric times it also inhabited the mainland of Australia. It is a rather stocky animal with a bushy tail. The black coat is interrupted by a white band across the throat, another across the rump and a white spot on each side of the body. The devils have short powerful jaws with heavy teeth.

The tiger cat (*Dasyurops*) is almost as large as the Tasmanian devil but is slender, about 20 in. long and much more active. Its colour is deep reddish-brown, both the body and tail being covered with white spots. These dasyures are excellent climbers, very elusive. Their diet consists almost entirely of meat; they stalk birds much like a cat and are extremely destructive of poultry. The lower jaw of another genus, *Glaucodon*, has been found in the Pleistocene of Victoria. It reflects relationships to both *Dasyurops* and *Sarcophilus*.

The native cat (*Dasyurus quoll*) is much smaller, its total length being about 13 in. It is less arboreal than, but otherwise as active as, the tiger cat. There are two colour phases; one is black, the other grayish tan. It differs from the tiger cat in having larger white spots only on the body and not on its bushy tail. The native cat is cunning and is often found near human habitation. *Dasyurus* is distributed along the east coast of Australia and in Tasmania.

In central and western Australia are two genera, *Dasyurinus* and *Satanellus*, that are closely related to *Dasyurus*. These spotted dasyures retain the first digit in the hind foot, whereas in *Dasyurus* that digit is missing. In some classifications *Dasyurops*, *Dasyurinus* and *Satanellus* are included in the genus *Dasyurus*.

Two other rat- or weasel-sized dasyures are the buff to reddish-brown *Dasyuroides* and *Dasyercus*. They are desert forms with large auditory bullae and no spots. *Dasyercus*, the mulgara or crest-tailed pouched "mouse," is distinguished from the other genus in having the tail thick just beyond the peduncle base and the terminal brush developed only on the dorsal side. Members of both genera are primarily carnivorous but also eat insects.

The dibbler or little speckled dasyure of southwestern Australia (*Parantechinus*), so named because the black body hair has long white tips, apparently is extinct. One of its most conspicuous features was the heavy covering of hair over about one-third of the base of the tail. The fat-tailed dasyure (*Pseudantechinus*) is found in the rocky deserts of central and northern Australia. In the mountains of New Guinea are two closely related, dark-coloured genera *Neophascogale* and *Phascosorex*. *Phascosorex* may be distinguished by the slender black dorsal stripe. The long faces of these dasyures give them the appearance of tree shrews. *Myoictis*, also restricted to New Guinea, comprises short-faced dasyures, with the pelage usually rufous, chestnut or nearly black and with three, slender, black dorsal stripes.

Planigale ingrami subtilissima (considered by some as referable to the genus *Antechinus*) is probably the smallest of any known marsupial, with a total length of 2½ in. One of the conspicuous features of this tiny, brownish-gray dasyure is the marked dorso-ventral flattening of the skull, an adaptation that allows these animals to find shelter in narrow cracks in the ground or between rocks. They have been found in central, northern and northwestern Australia.

Sminthopsis, another genus of small dasyures, are widely distributed in Tasmania, Australia, southern New Guinea and the Aru Islands. These delicately constructed, large-eared forms are ter-

restrial. They may conceal themselves under debris, logs, rocks or in holes in the ground. They are primarily insectivorous, but also are carnivorous and even cannibalistic. In central Australia during favourable seasons, they may be seen in the gibber (gravel) deserts at night, scurrying about in considerable numbers searching for insects.

The somewhat larger reddish-brown *Antechinus* species are equally widely distributed but are not as well adapted to desert environments. The skulls are wider than in *Sminthopsis* but not flattened as in *Planigale*, and the median upper incisors are enlarged. The tails have short hairs and are rather ratlike. Antechines are mostly insectivorous but also eat flesh. These terrestrial dasyures seek protection in rock crevices and among rocks and logs.

The arboreal bluish-gray *Phascogale* is about the size of rats or weasels. The terminal half of the tail is covered with long black hairs. The skull is somewhat flattened dorsoventrally and the median upper incisors are larger than in *Antechinus*. In human habitation phascogales are known to kill chickens and ducks and therefore considered pests comparable to weasels and rats. *Murexia*, from the mountains of New Guinea, Japan and the Aru Islands is grayish-brown above, and in one species (*M. rothschildi*) has a broad black stripe down the back.

In many respects the most remarkable of all dasyurids are the little jerboa dasyures (*Antechinomys*). These leaping, insectivorous marsupials, with large ears, lengthened hind legs and very long tail are found in the Northern Territory and probably elsewhere in the Australian interior.

Except for having only four toes on each hind foot, *Antechinomys* superficially resembles *Sminthopsis*.

Tasmanian Wolf Family (Thylacinidae).—The marsupial wolf (*Thylacinus cynocephalus*) is the largest and most widely known of the dasyuroid marsupials. Although its distribution is

BY COURTESY OF AMERICAN MUSEUM OF NATURAL HISTORY

FIG. 7.—TASMANIAN WOLF (THYLACINUS), FROM A PAINTING BY CHARLES R. KNIGHT. IN THE AMERICAN MUSEUM OF NATURAL HISTORY

usually recorded as being restricted to Tasmania, it was represented on the mainland of Australia less than 26,000 years ago, and appears to have lived on New Guinea also. H. C. Reynolds has stated that the last certainly known marsupial wolf was killed in Tasmania in 1932. Laymen usually refer to them as tigers because of the black stripes across their rumps and backs. Originally feeding on kangaroo and wallaby, *Thylacinus*, with the settling of Tasmania, began preying on sheep, which led to its being hunted and killed at every opportunity.

The family relationships of this marsupial are still not fully understood. (Its classification with the extinct Borhyaenidae of South America has almost conclusively been disproved.) However, its characters display a most remarkable convergent evolution with the American borhyaenids. It seems reasonable to assume that the marsupial wolf and the dasyures arose from a common ancestry far back in Cenozoic time. Species from the Pleistocene of Australia have been named, but even if these species are valid they are very closely related to the Recent species. Many authorities place *Thylacinus* in the family Dasyuridae, but until the

VINCENT SERVENTY, COLEMAN & HAYWARD

FIG. 8.—NUMBAT, OR BANDED ANTEATER (MYRMECOBIUS)

Cenozoic ancestry is adequately known this classification cannot be confirmed.

Banded Anteater Family (Myrmecobiidae).—The marsupial anteaters, called also banded anteaters or numbats, are basically related to the dasyures. Nevertheless these animals are so specialized in the skull and in dentition that their family rank seems fully justified. No fossils are known. *Myrmecobius* comprises squirrel-sized forms. The pelage on the back is light to dark rufous, transversely banded with white stripes, and the tail is long and bushy. They are terrestrial marsupials but prefer forest areas where ants are abundant. The teeth are small and degenerate in structure, although there are supernumerary molars.

Pouched Mole Family (Notoryctidae).—The family Notoryctidae represents the marsupial "moles" of Australia. Only one genus, *Notoryctes*, and two species are known. They occur in the sandy deserts of central and western Australia. There they burrow along in the sandy soil about three inches below the surface in search of worms and grubs. These little marsupials display a remarkable convergence in their characters and habits with the placental golden moles (*Chrysochloridae*) of South Africa and the true moles (*Talpidae*) of the northern hemisphere.

The pelage of *Notoryctes* ranges from nearly white to a rich golden-red. The eyes are so degenerate they are not visible through the hair and the external ears are only small openings through the skin. A blunt snout and an abbreviated tail are both covered with leathery skin. The pouch opens backwards and there are epipubic bones. Without a fossil record it is not possible to conclude how closely *Notoryctes* is related to the basal stocks of the dasyuroids and to that of the bandicoots, but the absence of syndactyly in the hind feet suggests they are closer to the dasyuroids.

BANDICOOTS (PERAMELOIDEA)

Bandicoots in some respects look like rodents and in other ways resemble small peccaries or pigs. They range in size from that of

PAUL POPPER

FIG. 9.—A RABBIT BANDICOOT, OR BILBY (THYLACOMYS)

a large rat to that of a hare. The face is long, narrow and pointed. The pelage is rather coarse, although some forms have a soft underfur. The tail, usually of medium length—and in most forms sparsely coated with short hair—is not prehensile. Perameloids have one of the most primitive characters seen in any Australian marsupials: the retention of an incisor formula of $\frac{1}{1}$ (polyprotodont) in most of the genera. They have syndactylism in the hind foot: the proximal and median phalanges of the second and third digits are enclosed in the same sheath of skin. The pouch is directed backward. Usually two to four young are raised at a time. Bandicoots are terrestrial and prefer brushy or grassy habitats where they may scratch shallow runways that afford them some protection; the bilbies, however, live in the arid interior. On the whole bandicoots are omnivorous.

Bandicoot Family (Peramelidae).—Three of the most primitive genera (*Peroryctes*, *Micropteryctes* and *Rhynchomeles*) are restricted to New Guinea and adjacent islands; *Echymipera* has dispersed into the northern part of Cape York peninsula, Australia. A fifth primitive genus, *Perameles*, the common long-nosed bandicoots, has experienced a wide distribution. It and a more progressive genus, *Isoodon*, may be found in Australia, Tasmania and New Guinea. The specialized bilbies (*Thylacomys*), or rabbit bandicoots or pinkies as they are sometimes called, occur only in Australia; house cat-sized, they are the largest of the Peramelidae.

Both *Thylacomys* and *Perameles* are represented in the Late Pleistocene faunas of Australia. An extinct genus, *Ischnodon*, has been found in the Pliocene strata of South Australia. The most peculiar of all peramelids, however, is the extinct pig-footed bandicoot (*Chaeropus ecaudatus*). The common name is derived from the construction of the front foot, in which the second and third digits are of equal length and closely united. The nails, of equal size and length, give the appearance of cloven hoofs.

PHALANGERIDS (PHALANGEROIDEA)

The phalangeroid marsupials of Australasia are here divided into five families. Only a very hypothetical phylogeny, indicating possible ancestral relationships of this group to the other super-families, can be outlined until an adequate fossil record from the Late Mesozoic and Early Cenozoic has been compiled. The Phalangerioidea were probably derived from an ancestral stock that also gave rise to the Peramelioidea. Evidently in this early stock (in contrast to the Dasyuroidea) natural selection was toward syndactylism of the second and third digits in the hind foot. Subsequently one syndactyl stock led to the ancestors of the rat kangaroos, kangaroos, diprotodontids, wombats, koalas, marsupial ferrets and phalangers; the other syndactyl stock gave rise to the bandicoots.

Phalanger Family (Phalangeridae).—The phalangers, "opossums" or "possums" in Australia, are distributed throughout Australasia. This family represents one of the most inclusive groups of marsupials. For the most part the genera are readily recognized because of their distinct appearance. Phalangers are primarily but not exclusively arboreal; the big toe is opposable and the tail is prehensile or fringed laterally with stiff hairs.

Eudromicia is the most primitive of all the living genera of phalangers. It comprises in part the "dormouse possums," whose colour is rich brown above and creamy-white below. They feed on insects and blossoms, and construct their nests of soft bark in hollow limbs or sometimes under the linings of bird nests. The retention of the fourth molars and the double rooted first and second upper premolars distinguish them from the other dormouse possums, *Cercaetus*, to which they show a remarkable resemblance.

Another small phalanger is the pen-tailed phalanger (*Distoechurus*) of New Guinea. The most conspicuous feature in this form is the tail, in which the basal half is covered with hair and the distal half is nearly naked but fringed laterally with stiff hairs. Even more remarkable is the pygmy glider or feather tail (*Acrobates*). It is readily distinguished from the other small phalangers by flaps of skin that stretch from the elbow to the knee on each side. The back is dark brown and the under parts are white.

FIG. 10.—SQUIRRELLIKE FLYING OPOSSUM (*PETAURUS*) (LEFT) AT REST AND (RIGHT) IN A GLIDE SEEN FROM THE UNDERSIDE, SHOWING THE OUT-STRETCHED MEMBRANE EXTENDING FROM WRIST TO ANKLE.

This little acrobat is primarily restricted to the eucalyptus forests in Australia, where it feeds on the nectar from eucalyptus flowers. This diet, however, is supplemented with insects.

The remains of a tiny extinct phalanger called *Burramys* has been found in the Guineacore fissure near the Wombeyan cave in New South Wales. The shape of the skull and the pattern of the molars resemble those in *Eudromicia* and *Cercaetus*, but the premolars are high and serrated.

The sugar glider or flying possum (*Petaurus*), in its volplaning adaptation, has converged with the flying squirrels of the northern hemisphere. The sugar glider is distributed in the forests of New Guinea, Australia and Tasmania. It varies in colour from dark brown to bluish gray; the gray ones have a brown stripe down the back and a predominantly brown, bushy, nonprehensile tail. The diet consists of insects, blossoms, fruits and buds. The brownish-gray to grizzled-gray Leadbeater's possum, (*Gymnobelideus*), though it has no gliding membrane, is more or less intermediate between the sugar glider and forms more adapted to climbing.

Most unusual is the striped possum (*Dactylopsila*). The longitudinally striped black-and-white coat makes this marsupial a conspicuous occupant of the trees in northern Queensland and in New Guinea. The evenly rounded tail is prehensile at the tip. The most outstanding specialization, however, is the elongation of the fourth finger, which is used primarily for probing grubs from crevices and cavities in wood. The striped possum prefers to eat the larvae of wood-boring beetles but also eats termites. A closely related genus, *Dactylonax*, is recognized from differences in the skull and in having a longer 4th digit.

The common phalangers or bush-tailed, or brush-tailed, possums (*Trichosurus*), which have adapted well to the occupation of their territory by civilized man, sometimes prove annoying at times when they seek shelter among the rafters of houses. These large possums have brown and gray colour phases. The thick bushy tail is naked below the tip and is prehensile. The rather pointed nose, large eyes and prominent ears are other outstanding features. Common phalangers are arboreal and nocturnal, like most marsupials. Normally their nests are constructed in large hollows of eucalyptus trees. They are primarily herbivorous but also will eat other foods. The gestation period in *Trichosurus vulpecula* is 17 to 18 days. One young is usually reared. One of the oldest fossil marsupials of Australasia is part of the skeleton of a brush-tail-like possum, *Wynyardia basiana*, that was found at Fossil Bluff near Wynyard, Tasmania. Fossils more closely related to the Recent species occur in the Pleistocene of Australia; others much older occur in the Middle Tertiary of South Australia.

Probably the ugliest of all marsupials are the lemurlike cuscuses (*Phalanger*), from which the family and superfamily names are derived. The unusual appear-

FIG. 11.—A COMMON PHALANGER (*TRICHOSURUS FULIGINOSUS*)

ance of the cuscus is due to the very short ears that scarcely extend beyond the hair. The outer half of the prehensile tail is covered with scales. The Queensland species is light brown with white spots. Other species, found in Timor, the Celebes and New Guinea, may be almost black, or have suggestions of spots; some are even white. *Wyulda*, the scaly-tailed possum, which is terrestrial and lives among rocks in northwestern Australia, is somewhat intermediate between the brush-tailed possums and the cuscuses.

The most extraordinary of all the phalangeroids is the little honey possum or long-snouted phalanger *Tarsipes*. They are found only in Western Australia. There are three dark brown stripes down the back, the sides and face are light brown and the under parts white. The long naked tail is prehensile. Extreme specialization is seen in the long narrow head and almost trunklike snout. In extracting nectar from blossoms the long tongue can be extended nearly an inch beyond the nose. The teeth are greatly reduced in number and are essentially vestigial.

Koala Family (Phascolarctidae).—The Phascolarctidae include the ring-tailed possums, greater gliders and koalas or native "bears." In this family the first and second digits of the hand are opposable to the third, fourth and fifth and the molars are adapted for chewing leaves.

Perhaps the least specialized of the genera in this family is *Pseudocheirus*, the ring-tailed possums. Their common name is derived from the long, tapering sparsely-haired tail that is usually curled in a prehensile manner. Ringtails are usually found in hilly country well above sea level; one species in New Guinea occurs as high as 12,000 ft. They do not extend as far along the forest-lined creeks into central Australia as do the brush-tailed possums. They construct dome-shaped nests in tree tops or may line the smaller hollows in limbs with leaves. The pouch contains two functional nipples and usually two young are raised. Fossils related to these possums have been found in the Middle Tertiary of South Australia.

The greater glider or great flying phalanger (*Schoinobates*) is a spectacular mammal. It is the largest of the gliding marsupials. The body alone is 18 in. long. The pelage is usually black above and white below, but a brown or gray back is not uncommon; others may be white. The tail is bushy and longer than the body. Greater gliders prefer heavily timbered country along the coastal highlands of eastern Australia, where they have been seen to glide as far as 120 yd. Usually they take off from the top of one tree and land on the trunk base of another. Their diet is almost exclusively tender leaves and blossoms. One young at a time is reared, although there are two nipples.

One of the most famous of all Australian marsupials is the koala (*Phascolarctos*). As with the greater glider only one species is known, although a rather distantly related genus, *Perikoala*, from the Tertiary of South Australia has been described. The koala, with its short tail and rather stocky body, so resembles the wombat that the two are considered by some students to have arisen from a common ancestor, perhaps not very far back in Cenozoic time. Others believe, however, that the koala is much closer to the ring-tails and greater gliders. In contrast to the other tree-dwelling marsupials, the pouch in the koala opens backwards. Only one young is born at a time. The koala is unique in having functional cheek-pouches. The ashy-gray pelage, fluffy ears, yellow, shoe-button eyes and black leathery nose are among its pronounced features. Koalas are so thoroughly arboreal in habits that they seem comfortable only among the branches of the trees.

The three genera included in this family are sometimes classified as belonging to the family Phalangeridae.

Marsupial Lion Family (Thylacoleonidae).—There has been much discussion on the probable feeding habits and the relationships of the so-called marsupial lion (*Thylacoleo*). Most students of marsupials agree, however, that it belongs in a separate family. Specimens of the cranium and lower jaws are well known, and parts of the limb bones and body skeleton have been found. *Thylacoleo* was about the size of an African lion. Its teeth were even more specialized for meat shearing than those in the true cats. For example, the large posterior premolars were as long as 2½ in. All the remaining teeth were greatly reduced, ex-

OWEN J. POE

FIG. 12.—SKULL AND RECONSTRUCTION OF THE HEAD OF THE MARSUPIAL LION (THYLACOLEO)

cept the upper and lower median incisors, which apparently were utilized in capturing other animals. These great carnivorous marsupials became extinct in Australia less than 26,000 years ago.

Rat Kangaroo Family (Potoroidae).—Although the genera referred to this family are closely related to the kangaroo family Macropodidae and are classified by some as a subfamily of that group, they apparently have represented a distinct lineage since Eocene time. They may be distinguished from kangaroos by, among other features, having conjoined masseteric and inferior dental canals that extend as far forward as the first or second molars and the frontal and squamosal bones of the skull in contact. The female urogenital system is more specialized than in the Macropodidae. The living genera are *Hyposiprymmon*, *Potorous*, *Bettongia*, *Aepyprymnus* and *Caloprymnus*. A Pleistocene genus, *Propleopus*, was much larger. A species of *Bettongia* and an undescribed genus occur in the Middle Tertiary of South Australia.

Kangaroo Family (Macropodidae).—The most widely known marsupials are the kangaroos. They include the gray (*Macropus*) and red kangaroos (*Megaleia*), euros or wallaroos (*Osphranter*), true wallabies (*Wallabia*), pademelons (*Thylogale*), rock wallabies (*Petrogale*), tree kangaroos (*Dendrolagus*) and the quokka (*Setonix*). The gigantic forms during the Pleistocene were *Procoptodon*, *Sthenurus*, *Protemnodon* and two species of *Macropus*. *Prionotemnus* is from the Pliocene, but the oldest kangaroos come from rocks probably as old as Miocene.

Like the rat kangaroos, the macropodids are adapted for jumping. They have long hind legs and long tails for balance. The forelimbs and hands function somewhat like those in primates, but the digits are equipped with sharp claws and the thumbs are not opposable. The principal digit in the hind foot is the fourth, the fifth being somewhat reduced; the syndactyl second and third are reduced to splinters but still bear tiny claws, and the first is absent. *Procoptodon* and *Sthenurus* differ from the other kangaroos in having lost all but the fourth digit. (See KANGAROO.)

Diprotodontidae.—The largest of all marsupials was the extinct, huge *Diprotodon optatus*. It was built something like a huge ground sloth, and rivaled some mastodonts in size. Special dentition included the large, chisel-shaped median incisors and molar teeth, somewhat like those in certain kangaroos or tapirs, composed of two cross-crests. *Diprotodon* was probably abundant in Australia in the Late Pleistocene and subrecent time. Its remains have been found in levels contemporaneous with man. It has been estimated that there are at least 1,000 skeletons of these animals within an area of 20 acres, where they bogged down in an old mound spring at Lake Callabonna in South Australia. At least two other genera, *Nototherium* and *Euowenia*, representing much smaller diprotodontids also occur in the Australian Pleistocene faunas. *Palorchestes* also of the Pleistocene, previously considered as the largest of all kangaroos, is now known to be a diprotodontid.

This family, like the Macropodidae, has had a long Cenozoic history in Australia. *Meniscophus* is known from the Pliocene, and remains of a rather primitive undescribed genus and species are thought to be as old as Oligocene. It appears that all known diprotodontids were herbivorous. The family may have been an early offshoot of the phalangeroid stock and perhaps was distantly related to kangaroos and wombats.

Wombat Family (Vombatidae).—The wombats are remarkably woodchucklike in appearance and habits. They are, however, considerably larger. Wombats differ from all other marsupials in their single pair of ever-growing upper and lower incisors, and in

their rootless, high-crowned cheek teeth. Some wombats are 15 in. high at the shoulder. They resemble koalas in having no tails; some authorities consider the koalas and wombats to be closely related.

Wombats are powerful diggers, sometimes constructing tunnels 100 ft. long. Colonial nests in these underground excavations are lined with soft bark. Wombats are both diurnal and nocturnal in habit. Their diet is mostly grass, which is grazed short for a considerable distance around their warrens. Although there are two nipples in the pouch, there is usually only one young born at a time. Constituting the family are: the common or naked-nosed wombat (*Vombatus* or *Phascolomys*); the hairy-nosed wombat (*Lasiorninus*); and the Queensland wombat (*Wombatus*). During the Pleistocene there was a giant wombat, *Phascolonius*, which was as large as a black bear.

MARSUPIAL MOLE (*Notoryctes typhlops*), a small burrowing animal from central South Australia, constituting a family, Notoryctidae, of the pouched mammals or marsupials (see MARSUPIAL). It resembles the true mole, family Talpidae, in size and appearance but is not a relative (see MOLE). Neither ear conches nor eyes are visible externally. Except for the horny skin on the nose and on the stumpy leathery tail, the body is covered with long, silky, golden-yellow hair. When awake, the marsupial mole is extremely active, searching almost continuously for worms, insects, etc. It feverishly devours its food and abruptly falls asleep, only to awaken shortly and resume its frenetic search. The forefeet are wonderfully adapted to burrowing, the third and fourth toes being armed with enormous claws.

MARSUPIAL MOUSE, a name for small members of the family Dasyuridae (see MARSUPIAL); most belong to the genus *Phascogale*, the broad-footed pouched "mice." There are more than 12 species, none larger than a rat. Females of several species have pouches, but there are folds of skin only around the mammae in other forms. Marsupial mice are found throughout Australia, Tasmania, New Guinea and the Aru Islands.

MARSUPIAL WOLF (*Thylacinus cynocephalus*), the largest carnivorous marsupial, resembling a wolf but smaller. Also called Tasmanian "wolf," "tiger" or "hyena," it is confined to Tasmania (perhaps extinct), but fossils show it was on the Australian mainland in the Pleistocene. Its face is sharp and foxlike. Grayish brown, its entire back is marked with transverse, blackish-brown bars. The pouch opens toward the hind quarters; it bears two to four young, carrying them for about three months. It feeds on wallabies, small mammals and birds. When sheep were introduced, it preyed on them; as a countermeasure, the marsupial "wolf" was nearly exterminated by man.

See also MARSUPIAL.

MARSYAS, a legendary Greek figure of Anatolian origin. According to the Greek legend Athena had invented the oboe and threw it away in disgust because it distorted the features. Marsyas found it and, having acquired great skill in playing the instrument, challenged Apollo to a contest with his lyre. Midas, king of Phrygia, who had been appointed judge, declared in favour of Marsyas, and Apollo punished Midas by changing his ears into ass's ears. In another version, the Muses were the judges, and

they awarded the victory to Apollo, who tied Marsyas to a tree and flayed him alive. In Rome a statue of Marsyas, a favourite art subject, stood in the Forum, and this was imitated by Roman colonies and came to be considered a symbol of autonomy.

MARTELLO TOWER, a defensive work whose name is a corruption of that of Cape Mortella in Corsica, where a circular tower of this kind was captured only with great difficulty in 1794 by British forces supporting Corsican insurgents against the French. With the threat to England of invasion by Napoleon Bonaparte in 1803, the duke of York, as commander in chief, recommended this type of tower for coast defense, and 74 Martello towers were therefore erected on the most vulnerable stretch of the English channel coast. They were from 30 to 40 ft. high, with walls 9 ft. thick on the seaward side, and surrounded by a deep ditch. Entry was effected by a small, rear door at the head of a 20-ft. ladder. A platform held two howitzers and a swivel gun; a powder magazine and living quarters were below. The French built a few *tours modèles* of similar design, and others were built in the United States and Canada. Martello towers lost most of their value with the advent of powerful naval guns. (R. C. H.)

MARTEN, several species of the weasel-like genus *Martes* of the mammalian carnivore family Mustelidae (see CARNIVORE). The American marten (*M. americana*) is similar to the pine marten (*M. martes*) of north and central Europe and the British Isles.

EDWIN C. PARK FROM NATIONAL AUDUBON SOCIETY

MARTEN (*MARTES AMERICANA*)

The marten is a cat-sized animal with a long, somewhat bushy tail, and a lithe and slender body. The legs are short, the neck long and flexible and the ears short and rounded. The rich, dense and lustrous fur with stiff and shiny guard hairs is highly valued; the coat is golden brown shading to blackish on the feet and tail tip and to orange on the throat. The pine marten is dark brown with a tawny throat. Martens are bloodthirsty and rapacious, feeding on small mammals, birds and occasionally birds' eggs. They live in forests, especially in rocky areas, and climb trees as easily as a squirrel. Sexual maturity is reached at two years. Most species mate in late summer, one to five young being produced the following spring. In northern species the gestation period is prolonged (from 220 to 358 days according to species and locality). The gestation period may be markedly shortened by increasing the hours of light per day.

In the same genus the dark sable (*M. zibellina*), which inhabits Siberia, has the most valuable fur. The beech or stone marten (*M. foina*), occurring from central and southern Europe to China, is a paler species. *M. melampus* is found in Japan. The large fisher or pekan (*M. pennanti*) occurs in North America. The large yellow-throated marten (*C. flavigula*), occurring from India and China to Java, belongs to the closely related genus *Charronia*. See also FUR. (K. R. KN.)

MARTENS, FËDOR FËDOROVICH (FRÉDÉRIC FROMM-HOLD DE MARTENS; FRIEDRICH VON MARTENS) (1845-1909), Russian jurist and author of works on the European penetration of Asia and Africa, was born at Parnu, in Livonia, Estonia, on Aug. 27, 1845. In 1868 he entered the Russian ministry of foreign affairs and in 1872 was made professor of public law in the Imperial School of Law and the Imperial Alexander lyceum, a post he held until 1905. In 1874 he started special juristic work for the Russian government. His work on the right of private property in war appeared in 1869, and that on the office of consul and consular jurisdiction in the east in 1873 (German trans., 1874). These were the first of a series of studies which won Martens a worldwide reputation and enhanced that of the Russian school of international jurisprudence.

Recueil des traités et conventions conclus par la Russie avec les puissances étrangères (15 vol., 1874-1909), edited by him, is the greatest of the series; published in Russian and French in parallel columns, it contains not only the texts of the treaties between Russia and other countries but also histories of the diplomatic conditions of which the treaties were the outcome, these being based upon unpublished Russian documents.

Martens' original work includes books on Russia and England in central Asia (1879), on Russia's conflict with China (1881), on the international law of civilized nations (1882), on the Egyptian question (1882) and on the African conference of Berlin and the colonial policy of modern states (1887).

Repeatedly chosen to participate in international arbitrations, Martens acted in the disputes between Mexico and the United States—the first case to be determined by the permanent tribunal at The Hague—and that between Great Britain and France over Newfoundland in 1891. He played an important part in the negotiations between his own country and Japan which led to the peace of Portsmouth (Aug. 1905) and prepared the way for the Russo-Japanese convention. He was employed in laying the foundations for The Hague conferences and was one of the Russian plenipotentiaries at the first conference and president of the fourth committee—that on maritime law—at the second conference. He was judge of the Russian supreme prize court established to determine cases arising during the Russo-Japanese War of 1904-05. He died at Valga, in Livonia, on June 19, 1909.

See T. E. Holland in *Journal of the Society of Comparative Legislation* (Oct. 1909), where a list of writings of Martens appears.

(E. H. Ld.; X.)

MARTENS, GEORG FRIEDRICH VON (1756-1821), German jurist and diplomat, the original editor of the principal printed collection of treaties of the world, was born at Hamburg on Feb. 22, 1756. He was educated at the universities of Göttingen, Regensburg and Vienna and became professor of jurisprudence at Göttingen in 1783 and was ennobled in 1789. In 1814 he was appointed privy cabinet counselor (*geheimer Kabinettsrat*) by the king of Hanover and in 1816 went as a representative of the king to the diet of the new German confederation at Frankfurt, where he died on Feb. 21, 1821.

Martens' major work, *Recueil des traités* from 1761, had been preceded by *Histoire diplomatique des traités*, covering the period from the end of the 16th century to the peace of Amiens (1577-1802). The first seven volumes of *Recueil des traités* were published 1791-1801 and were followed by four supplementary volumes partly edited by his nephew Karl von Martens. These were followed by *Nouveau recueil général des traités*, of treaties subsequent to 1808, in 16 vol. (1817-42) edited by G. F. von Martens, K. von Martens, F. Saalfeld and F. Murrhard; this last work was subsequently continued under other editors (2nd series, 20 vol., 1843-75; 3rd series, 35 vol., 1876-1908; 4th series, 41 vol., 1908-44).

Of Martens' other works the *Droit des gens*, first published in 1788, is probably the most famous. (E. H. Ld.)

MARTHA'S VINEYARD, an island off the southeastern coast of Massachusetts, about four miles across Vineyard sound from the mainland of Cape Cod. Long a leading fishing and whaling area, the island is now almost entirely devoted to the summer tourist and recreation industries.

The island is nearly 20 mi. long, ranges from 2 to 10 mi. in width and represents largely the terminal moraine of a continental ice sheet. There is rolling to hilly country along the northeastern side, stretching out to nearly level plains in the south and east. The highest point is only 311 ft. above sea level. The ocean has been very active in shaping the coast line, sealing off the many inlets along the south shore and building up long beaches and spits. The many-coloured clay bluffs at Gay Head are among the island's spectacular sights.

Martha's Vineyard probably was sighted by many early explorers, but the first known record was by Bartholomew Gosnold in 1602. Granted to Thomas Mayhew of Massachusetts, the island was first occupied in 1642; it was under the jurisdiction of New York until 1692. There were early attempts at agriculture, salt evaporating, brickmaking and the smoking of fish. Fishing, which became an important source of revenue, led to the development of whaling and foreign trade, the two activities that eventually dominated the 18th and part of the 19th centuries. At one time the island boasted the world's largest sperm oil candle factory.

Advances in technology and a disadvantageous location terminated both of those trades, but the island's quaint old villages, Colonial architecture, scenic beauty and sandy beaches, as well as its protective coves for yachts and sailboats made Martha's Vineyard nearly ideal for summer vacationers and visitors.

The island itself contains six small towns: Tisbury, Oak Bluffs, Edgartown, West Tisbury, Chilmark and Gay Head, the latter occupied almost entirely by Indians. Together with the adjacent Elizabeth Islands and No Mans Land, the island forms Dukes county, Mass. (G. K. L.)

MARTÍ, JOSÉ JULIÁN (1853-1895), Cuban writer and patriot who is considered his country's greatest hero and, like Simón Bolívar, is a symbol of liberty throughout Latin America, was born in Havana on Jan. 28, 1853. He attended the schools of San Anacleto and San Pablo, the latter under the direction of the poet Rafael María de Mendive, who helped him continue his education in the Instituto de Segunda Enseñanza de la Habana and became Martí's main source of inspiration as well as his teacher and benefactor.

Mendive and Martí sympathized with the cause of the Cuban patriots, headed by Carlos Manuel de Céspedes, when fighting broke out on Oct. 10, 1868 (*see CUBA: History*). The following year Mendive participated in an uprising at the Teatro Villanueva, as a result of which he was imprisoned and his school closed. A short time later Martí was also detained; after serving six months of hard labour, he was finally deported to Spain on Jan. 15, 1871.

There he continued his education, receiving both his licentiate in law and a master of arts degree from the University of Saragossa in 1874. He fled to France and then in 1875 to Mexico City, where he wrote for the press. He visited Cuba briefly in Jan. 1877 and then went to Guatemala, where he taught literature and achieved fame as an orator. In Dec. 1877 he married Carmen Zayas Bazan the daughter of an exiled Cuban.

Not happy with political conditions in Guatemala, then ruled by president-dictator Justo Rufino Barrios, Martí and his wife returned to Cuba in Dec. 1878, but because of his continued political activities, Martí was again exiled to Spain, in 1879. This time, however, he remained there only two months, again going to France, and then to New York city. In 1881 Martí went to Venezuela. His articles in the *Revista Venezolana*, which he founded, did not meet with the approval of Venezuela's dictator Antonio Guzmán Blanco, and, less than five months after he had departed, Martí was forced to return to New York city, where he remained, except for occasional trips to Florida and the Caribbean, until the year of his death.

During those years Martí continued publishing for Latin-American newspapers. In August of 1881 he began to write a regular column for *La Opinión Nacional* of Caracas and in July of 1882 one for *La Nación* of Buenos Aires; his many articles in the latter made him famous throughout Latin America.

As a result of a disagreement with the Cuban revolutionary leaders Máximo Gómez and Antonio Maceo, Martí withdrew from politics for three years. In 1877 he regained their confidence and

returned with renewed energies to the fight for Cuba's independence. In 1892 Martí was elected *delegado* (he refused to be called president) of the new Partido Revolucionario Cubano, which he had helped to form, and, making New York city his centre of operations, began preparing for the invasion of Cuba.

On Jan. 29, 1895, the order was given to start the attack. Martí left New York two days later and went to Santo Domingo, accompanied by Máximo Gómez and other revolutionary leaders. They landed in Cuba on April 11. Shortly after, on May 19, 1895, Martí was killed in the skirmish that took place on the plains of Dos Ríos, Oriente province.

Literary Work.—Martí had neither the time nor the tranquillity to create outstanding works of art, but with few exceptions his writings have the enduring quality found in the books of great authors. He began writing at an early age: at 15 he composed several poems; at 16 he published his first newspaper, *La Patria Libre*, and wrote a dramatic poem, "Abdala"; his political essay *El presidio político en Cuba* was published while he was an exile in Madrid, in 1871. Outstanding among his works are his poems, his letters, his literary portraits, and his essays interpreting Latin America and the United States.

As a poet, Martí is recognized as one of the precursors of the modernistas (see IBERO-AMERICAN LITERATURE: *The Modernists*). His first significant poems, composed for his son, appeared in book form in 1882, under the title *Ismaelillo* ("Little Ismael," his son's name). The 15 poems are given unity by the central theme, paternal love, and by the simplicity of form and the sincerity of expression, characteristic of all of Martí's poetry. Another collection, *Versos libres* (written between 1878 and 1882, published 1913), was devoted to the theme of freedom. Different in tone are the poems of his best-known collection, *Versos sencillos* (1891), in which the themes of love, friendship and resignation predominate.

In *Amistad funesta* (1885), considered the first modernista novel, Martí created a sophisticated, refined and elegant atmosphere characteristic of this type of literature, but the work now has only historical value. He also translated Helen Jackson's *Ramona* and Hugh Conway's then popular *Called Back*, under the title *Misterio*. Much more successful than his original novel were his short stories, included in the four issues of *La edad de oro* (1889), a review published by Martí for the children of Latin America. His dramatic works ("Abdala," 1869; *Adúltera*, 1872-74; *Amor con amor se paga*, 1875) lack the high quality of his poetry and his narrative compositions.

It is in the essay, however, that Martí's greatest contribution to Latin-American letters is to be found. Outstanding are those he wrote on Cecilio Acosta (1881), Emerson (1882), Juárez (1884), General Grant (1885), Whitman (1887), Heredia (1889), *Nuestra América* (1881), *San Martín* (1891) and *Bolívar* (1893). His essays, in which original thoughts are expressed in an intensely personal style, were influential in bringing about an innovation in Spanish prose writing. At the same time, they were instrumental in promoting better understanding between the United States and Latin America, as well as between the Latin-American nations themselves. Martí considered himself a citizen of the Americas and his writings on the subject possess permanent value. His works, in general, reflect his exemplary life, his kindness, his originality, his love of liberty and justice and his deep understanding of human nature.

MARTIAL (MARCUS VALERIUS MARTIALIS) (c. A.D. 40-c. A.D. 104), Roman epigrammatist, brought the Latin epigram to perfection and provided in his poems a picture of Roman society under the early empire which is remarkable both for its completeness and for its accurate portrayal of human foibles. His birth-

place was Bilbilis, in Hispania Tarraconensis, of which he writes (in i, 61, 11-12): *te, Liciniane, gloriabitur nostra/nec me tacebit Bilbilis* ("of thee, Licinianus, our Bilbilis shall boast, nor will she keep silent about me"). His birthday was March 1, *Martem mearum principem Kalendarum* (x, 92, 10). Martial made much use of the mordant epigram bearing a sting in its tail. Frequently this sting consists merely of a single unexpected word. Poems of this kind exercised a great influence on the history of the genre in the literature of England, France, Spain and Italy. Though some of the poems are devoted to scenic descriptions, most are about people—emperors, public officials, writers, philosophers, lawyers, teachers, doctors, fops, gladiators, slaves, undertakers, gourmets, spongers, senile lovers and revolting debauchees.

Life at Rome.—In A.D. 64 he came to Rome, where, apart from a brief visit to Cisalpine Gaul in 88, he made his home for 34 years. There he sought the protection of his fellow Spaniards, the Senecas and Lucan, but, as they were involved in the Pisonian plot of 65, this attachment was of short duration. Virtually nothing is known of his career during the next 15 years. In 80 was published the *Liber Spectaculorum*, containing 33 epigrams celebrating the shows held in the Colosseum, an amphitheatre in the middle of the city begun by Vespasian and completed by Titus in 79. Living at first in rather humble circumstances (i, 117, 7: *scalis habito tribus sed altis*, "I live up three staircases, and high ones too"), he gradually made headway and was able to have, in addition to his town house on the Quirinal (x, 58, 10: *vicinosque tibi, sancte Quirine, lares*, "And my house near to you, sacred Quirinus"), a small country place at Nomentum, in the Sabine territory (vi, 43, 3-4: *me Nomentani confirmant otia ruris/et casa iugeribus non onerosa suis*, "leisure in the Nomentan countryside restores me and a cottage not too big for its acres"). He won the ear of the court and received from Titus and Domitian, though he was not a father, the *ius trium liberorum* (the rights of a father of three children), a privilege which allowed a person to hold a public office before his 25th year and to be exempted from public burdens. *Rumpitur invidia tribuit quod Caesar uterque/ius mihi natorum* ("he is consumed with envy because both Caesars have granted me a father's rights"), he wrote in ix, 97, 5-6. He also, probably without having served in the army, obtained a military tribuneship and, despite his lack of means, the dignities of an *eques Romanus* ("Roman knight"). In 84 or 85 appeared two books of epigrams (in modern editions, books xiii and xiv) entitled *Xenia* and *Apophoreta*, two-line mottoes for presents distributed at the festival of the Saturnalia, in December. In 86 were issued books i and ii of the *Epigrams*. Between 86 and 98, when Martial returned to Spain, new books of the *Epigrams* were brought out more or less at yearly intervals. When the poet left Rome for his birthplace (xii, 18, 7-9: *multos repetita post Decembres . . . Bilbilis*, "Bilbilis sought again after many Decembers") he lived on an estate presented to him by his friend Marcella, a Spanish lady of whom he writes warmly in xii, 21 and 31. There he wrote and published the 12th and last book of his *Epigrams* and soon after died. Pliny the Younger, in a letter of 104, describes his feelings on hearing of the poet's death: "I hear that Valerius Martialis has died and I am grieved. He was a man of ability, sagacity and ardour, whose writing displayed wit, acrimony and no less good-nature. When he was leaving Rome I presented him with a parting gift, a tribute both to his friendship and to the lines he wrote about me." The poem referred to is x, 19, and Pliny quotes the last ten lines (12-21).

Literary Friendships.—At Rome, Martial seems to have enjoyed the friendship of the leading literary men of his time. Pliny, Lucan and the Senecas have already been mentioned. Lucan is eulogized in vii, 22; vii, 21 and 23 are addressed to Polla Argentaria, Lucan's widow. The loyalty of Maximus Caesonius to the exiled Seneca is recorded in vii, 44 and 45. Quintilian is addressed in ii, 90, a poem which seems to express the poet's attitude to life:

Quintilian, distinguished trainer of our wayward youth, Quintilian, glory of the Roman gown, pardon me if I, though still poor, yet not made useless by the years, am quick to enjoy life. No man is quick enough really to enjoy life. If a man is eager to surpass his father's

income, if he wants to crowd his halls with family busts, let him put off the job of living. My delight comes from the hearth and the roof-tree that does not object to sooty smoke, from a living spring and an untrained grass-plot. Give me a well-fed home-born servant, a wife who is no bluestocking, nights blessed with sleep and days innocent of litigation.

Silius Italicus, addressed in iv, 14, 1 as "pride of the Muses' sisterhood," is mentioned also in vi, 64, 10; vii, 63, 1-2; ix, 86, 1-2; and xi, 48 and 49. To Valerius Flaccus, another epic poet, there are references in i, 61, 4; i, 76; and iv, 42 and 49. For his relations with his true friend Juvenal see vii, 24 and 91; xii, 18. Martial never speaks of Statius, nor Statius of Martial. J. Wight Duff has suggested that "incompatibility of temperament" may explain this strange silence.

Form of the Epigram.—Martial wrote 1,561 epigrams in all. Of these 1,235 are in elegiacs, 238 in hendecasyllables and 77 in scazons or "limping iambics." The remainder includes pure hexameters (e.g., i, 53), pure iambic trimeters (e.g., vi, 12), iambic trimeter alternating with iambic dimeter (e.g., i, 49) and scazons alternating with iambic dimeters (e.g., i, 61). Occasionally Martial's epigrams are much longer than those of the Greek anthology (see ANTHOLOGY): 51 scazons make up iii, 58, while vi, 64 consists of 32 hexameters.

The elegiacs owe much to Ovid, though Catullian influence is probably to be discerned in the polysyllabic endings of pentameters. On Catullus also are based the hendecasyllables and scazons; but Martial's scazons begin more rigidly with a spondee. "Echoing verses" and involved patterns of various kinds are not uncommon (cf., i, 32, 67, 77, 79; ii, 6, 33, 41, etc.). Puns, parodies, Greek quotations and ingenious ambiguities enliven Martial's pages. A type of epigram familiar to all is illustrated by i, 28, where the apparent contradiction of an insult masks an insult far more subtle: "If you think Acerra reeks of yesterday's wine, you are mistaken. He invariably drinks till morning."

Servility and Adulation.—Many readers of Martial are repelled by his flattery of any, especially the rich and powerful, who could fill his stomach or his purse. His frequent pleas for more and better presents from patrons and above all his use of the official title "Lord and God" toward Domitian cause a disgust not entirely warranted by the facts of history. For Martial, a poet known to the imperial court, to refuse extravagant homage might well have been suicidal. As for his begging verses, objectionable though they are, they must have paid dividends or the practice would have been abandoned. The poems on Domitian, disfigured by grotesque mythological conceits, are utterly foreign to Martial's usual direct style and are among his worst efforts.

Obscenity.—Byron asked, "What proper person can be partial? To all those nauseous epigrams of Martial?" The Delphin editor abstracted the foulest verses and lumped them together at the end of the book. Opinions are bound to vary on the proportion of the indescribably salacious to the tolerably wholesome; it is certainly more than a tenth and considerably less than a quarter. Martial repeatedly warns his readers that his poems are not for the squeamish. He protests that though his page is licentious, his life is decent: *lasciva est nobis pagina, vita proba* (i, 4, 8). Catullus and Ovid had made similar distinctions before him: Apuleius and Ausonius were to do so in later generations. Martial hints more than once that he is far from being the worst of offenders.

Sentiment in Martial.—A genuine love of natural scenic beauty is seen in iv, 44 (lament for the devastation caused by the eruption of Vesuvius, A.D. 79); iv, 64 (view of Rome from a friend's estate); and x, 30 (seashore at Formiae). Tenderness toward slaves, inherited perhaps from the precept and practice of Seneca and Pliny, marks i, 88 and 101, both of which are funeral epigrams. Other sepulchral poems include v, 34 (on Erotion, a girl not yet six); vi, 85 (on Camonius Rufus, a lad of 20); and xi, 13 (on Paris, a celebrated actor, put to death by Domitian). The warmth of his friendship is to be seen in three famous epigrams, all addressed to Julius Martialis (i, 15; v, 20; and x, 47). The first ends with the advice—*sera nimis vita est crastina: vive hodie*, "live for to-day: tomorrow is too late." The second contains the sundial motto about the fleeting hours—*percutit et*

imputantur, "they perish and are scored against us." The third, which has been translated by a dozen English poets, consists of a comfortable recipe for happiness. Another, iv, 13, is a charming little epithalamium, while x, 23 is a serene picture of the peaceful old age of one who, by reliving his well-spent days, doubles his life's span.

MARTIAL LAW. This term is one of rather doubtful significance in the English legal system, but is fairly well defined in the United States. It can be argued plausibly, but scarcely with conviction, that the English legal system does not know of, and makes no provision for, martial law, and that it is merely a term relating the common law right to resist force by force to a state of war, whether civil or external. This view seems to be implicit in a dictum of Chief Justice Thomas Molony in *R. v. Strickland* (1921 2 Irish Reports 334) that "the term 'execution of Martial Law' is now nothing more than a convenient label for the state of affairs which exists when the military take exceptional measures to suppress an insurrection." In the words of Sir Frederick Pollock, "So-called 'martial law,' as distinct from military law, is an unlucky name for the justification by the common law of acts done by necessity for the defence of the Commonwealth when there is war within the realm."

On the other hand, the learned editors of D. L. Keir and F. H. Lawson's *Cases in Constitutional Law* express the view that the military authorities "have the right not to be interfered with *durante bello*, and this right belongs, it is to be conceived, exclusively to the regularly constituted military forces." If this argument be correct, and this right does indeed belong exclusively to the lawfully constituted military authorities, then martial law is something more than a "convenient label." Indeed, Chief Justice Molony himself, in the case referred to above, gives the most forcible answer to his own definition, for he stated elsewhere in his judgment that, "We hold that when a state of things does exist which justifies the 'execution of martial law,' and is proved to our satisfaction, our hands are tied . . . the courts have recognized frankly that when a state of war exists—and they have not relinquished the right of adjudicating on that point—they must 'accept the consequences.'" It may be that martial law can be defined as a stage intermediate between law and anarchy, in which the normal administration of the law having broken down, the authority appointed in accordance with law maintains order by summary methods.

In any event, martial law must be sharply distinguished from military law, which is the law governing the armed forces whether in war or peace; confusion has been caused by the fact that some of the older writers, for instance, Sir Matthew Hale in his *History of the Common Law of England*, used the term "martial law" in relation to what is now called "military law."

Martial law, in the modern sense, seems to have three different aspects in the relationship of the military authorities to (1) subjects and nonenemy aliens, (2) enemy aliens at home and (3) enemy aliens abroad. No very serious problems are presented by (2) and (3). As for (2), it is difficult, as Sir W. Holdsworth has observed, to see by what authority these could be tried by English courts, though in practice, and on the authorities, it would appear that, once the ordinary courts were satisfied that a state of war existed at the relevant time, they would not inquire into any acts done by the military authority, at any rate unless it could be established that they were done in ill faith. As for (3), the crown has an "absolutely free hand," though in the light of the Nürnberg trial and the trials of lesser war criminals, the duke of Wellington's remark that martial law merely means "the will of the general who commands the army" requires some qualification: that will must be exercised in accordance with international law and the conventions of civilized warfare—however these may be interpreted from time to time.

Constitutionally and historically, the first aspect, namely the relationship of the military authorities in whom the execution of martial law is vested, toward the subjects and nonenemy aliens who are entitled to the protection of the crown, is the most important. It gives rise to three main questions: (1) What are the circumstances, if any, that lawfully give rise to the suspension of normal civil rights? (2) In what circumstances, if any, will the normal courts review the decisions of tribunals set up by the military authorities to help them in the exercise of their powers? (3) What remedies, if any, has the subject against abuse or excess of their powers on the part of the military authorities?

Circumstances Giving Rise to Martial Law.—As Chief Justice Molony pointed out in the Irish judgment referred to above, the courts have not relinquished the right of adjudicating on the question whether a state of war exists. In older authorities, the test that was applied seems to have been the simple one of whether the ordinary courts were sitting or not; if they were, for this purpose a state of peace was deemed to exist, and there was therefore no room for the declaration or execution of martial law. This rule, if it can be so termed, appears definitely to have been abrogated by the decisions of the judicial committee of the privy council in *Elphinstone v. Bedreechund* (1 Knapp. P.C. 316) and *D. F. Marais v. The General Officer Commanding the Lines of Communication of the Colony* (i.e., the Cape of Good Hope) (1902 Appeal Cases 109). In the latter case martial law had been proclaimed both in the district in which the petitioner, Marais, had been arrested, and in that to which he had been moved. In giving the judgment of the judicial committee, Lord Halsbury, the lord chancellor, said that they were "of opinion that where war is raging acts done by the military authorities are not justiciable by the ordinary tribunals, and that war in this case was actually raging . . . is sufficiently evidenced by the facts disclosed by the petitioner's own petition and affidavit . . . The fact that for some purposes some tribunals had been permitted to pursue their ordinary course is not conclusive that war was not raging." The conclusion Lord Halsbury drew was that: "The truth is that no doubt has ever existed that where war actually prevails the ordinary courts have no jurisdiction over the action of the military authorities," but that "doubtless cases of difficulty arise when the fact of a state of rebellion or insurrection is not clearly established."

These statements in Marais's case probably represent the high-water mark of the doctrine of the immunity of the military authorities from control by the civil power. But it may be remarked that even here, where the simple test of whether or not the ordinary courts are sitting was discarded probably once and for all, the right of the judiciary to consider whether, as a matter of fact, war was actually raging was vindicated by Lord Halsbury as it has been by other judges both before and since. On what criteria the courts would come to a decision today there does not seem to be much positive guidance. The test of an immediate local emergency seems to have been discarded. On the other hand, the decision of the house of lords in *Johnstone v. Pedlar* (1921 2 Appeal Cases 262) that it was "not a good defence to an action of tort brought by a friendly alien resident in the United Kingdom against an officer of the Crown in respect of the wrongful seizure and detention of the alien's property that the seizure and detention have been adopted and ratified by the Crown as an act of State" would seem, in spite of the rather special character of the facts, to warrant the conclusion that a mere state of general war, not involving a suspension of the normal machinery for the maintenance of order and the execution of justice, does not suffice to justify an arbitrary act done under colour of emergency.

Jurisdiction of the Courts Over Tribunals.—It seems to be well established that the normal courts will not review the decisions of tribunals set up by the military authorities to help them in the exercise of their powers because they do not recognize these tribunals as courts of law. Historically, the reason seems to be that acts done in pursuance of martial law were, in the words of Keir and Lawson, "withdrawn from the cognizance of the common law," and in consequence, although the crown's "executive acts escaped the interference of the judges, its power to do them did not in all cases receive judicial acknowledgment. It would ac-

cordingly be difficult at the present date to find authority for the view that such acts can legally be done under the Royal Prerogative." The leading authority in this field is the decision of the house of lords in *In re Clifford and O'Sullivan* (1921 2 Appeal Cases 570). In Dec. 1920 the commander in chief in Ireland declared the unauthorized carrying of arms to be punishable by death, and he authorized the general officer commanding in Cork to issue orders for the holding of military courts as might be necessary. In May 1921 Clifford and O'Sullivan, who were civilians, were tried by a military court on a charge of improperly carrying arms and were convicted and sentenced to death, subject to confirmation; they applied in the chancery division in Ireland for a writ of prohibition against the military court, the commander in chief and the general commanding in Cork on the ground that the court was illegal and had no jurisdiction to deal with the matter. On appeal to the house of lords the application was dismissed, on the ground, among others, that prohibition did not lie, because the officers constituting the court did not claim to act as a judicial tribunal in any legal sense.

Remedies of the Subject.—The question of remedies against the abuse or excess of their powers on the part of the military authorities is one on which there is very little authority. Granted that, as the 16th-century judges declared, "in time of war a man may justify making fortifications on another's lands without licence" (1 Dyer 36 b), what is the position if he does so not for the purposes of defense but to gratify a private spite against the landowner? Keir and Lawson have no doubt but that "evidently the Commander-in-Chief would be liable for acts done *mala fide* and not solely with a view to suppressing insurrection." This view is eminently sensible and accords with the common-law doctrine of using the minimum degree of force that is necessary to repel force. Then there is the question of the character of the necessity. Of this Keir and Lawson say that "Dicey's doctrine, that he [i.e., the military commander] must prove an immediate necessity for every act, is obviously too hard . . ." This view is not only sensible but accords with the decision in Marais' case that the emergency need not be for these purposes an immediate or local one.

The modern practice of taking emergency powers by statute makes the likelihood of these questions assuming importance in the future somewhat doubtful. But in the past they certainly had considerable importance. (W. T. Ws.)

United States.—In the United States, martial law is the temporary rule by military authority of a designated domestic area in time of an emergency when the civil authorities are unable to function or their attempt to continue functioning for the time being might endanger the state. It may be declared by a proclamation of the president or the governor of a state, but such a proclamation is not necessary. Martial law becomes effective when military authorities supplant the civil authorities. Although neither mentioned in the constitution nor defined by statute, martial law long has been recognized in the United States. Civil courts many times have been called upon to pass upon the validity of acts taken in pursuance of martial law, but they have not precisely defined its limitations.

Martial law, as noted above, is to be distinguished from *military law*, which is the law governing those in the military service; from *military government*, which is the military rule of conquered territories; and from situations in which military forces are called upon to assist the civil authorities in maintaining public order without the existence of martial law. Where the military forces are called upon only to assist, the civil courts continue to function, and members of the civilian population may be punished only for violations of the civil law, not for violations of military orders other than those in implementation of civil law. (See also MILITARY GOVERNMENT.)

The use of federal or state military forces to quell a domestic disturbance or to assist in the maintenance of order during a disaster, such as a flood or a tornado, does not of itself bring about a state of martial law. In sending federal troops into Pennsylvania in 1794 to put down the Whisky Insurrection, President Washington specifically admonished the commander of the troops

to enforce the law and deliver the insurgents to the regular courts for trial. During the labour trouble in the Coeur-d'Alene area of Idaho in 1899, the president sent federal troops to assist in the maintenance of order but directed that they support the civil authorities in the preservation of peace. Within a few hours after the initial shocks of the San Francisco earthquake of 1906, federal troops from a local garrison were assisting the civil authorities in maintaining order.

There have been cases in which governors of states have improperly declared martial law in order to accomplish political purposes. Such was the case in Texas in 1931 when the governor declared martial law to permit enforcement of a limitation upon the production of oil; his act was declared invalid by the United States supreme court in the case of *Sterling v. Constantin*. Two other examples occurred in the 1930s. In South Carolina the governor declared a state of "rebellion, insurrection, resistance and insurgency" in an attempt to depose state highway commissioners; in Oklahoma the governor sought to prevent further construction of a dam until demands of the state highway commission for reimbursement for the closing of roads were met. In both cases, the courts declared the acts of the governors invalid.

The justification for martial law is that civil authorities are unable to function, or that because of impending grave danger, it would be unsafe for them to function. The question as to the continued functioning of the civil courts is particularly important. In an area of active military hostilities, it is a practical impossibility for the civil courts to function. Where it is felt that their functioning should be suspended because of impending danger, a doubt may exist as to the necessity of the suspension. Immediately following the bombing of Pearl Harbor in 1941, for example, martial law was declared in Hawaii, the civil courts were closed and trials were by military courts. Although civil courts later were permitted to operate to a limited extent, martial law was not finally removed until late in 1944. In the case of *Duncan v. Kahanamoku*, which involved civilians tried by military courts in Hawaii, the U.S. supreme court found that there was no justification for suspension of the civil court functions at the time the accused civilians were convicted, but did not state the limit of martial law which the court would have found proper.

The U.S. constitution specifically recognizes that the privilege of the writ of habeas corpus may be suspended when in cases of rebellion or invasion the public safety may require it. This privilege requires that a person who is in confinement must be, upon his demand, brought before a court to determine the legality of his confinement. The privilege is suspended as an incident to martial law. During the period of martial law, the military commander rather than a civil court determines the propriety of the confinement. Thus a person believed dangerous to the state may be confined upon mere suspicion, without trial until the termination of martial law. During the Civil War, President Lincoln suspended the privilege in various localities, particularly in the vicinity of the nation's capital.

While martial law is in effect, persons charged with violations of either civil law or military orders may be tried by military courts commonly known as provost courts. The sentences adjudged by such courts are no longer effective after the termination of martial law.

The authority of the military commander, during a period of martial law, is virtually unlimited, but the commander later may be called upon to justify his actions. He may be personally liable to pay damages for acts which do not appear to have been reasonably believed necessary at the time the acts were undertaken. However, the commander is judged according to the facts as they appeared at the time rather than according to the way they appeared in the light of later developments. (J. K. G.)

MARTIGNAC, JEAN BAPTISTE SYLVÈRE GAY, VICOMTE DE (1778-1832), French statesman who led the government of Charles X from 1828 to 1829 and alienated the king by his moderate policies, was born at Bordeaux on June 20, 1778. In 1798 he acted as secretary to Sieyès; then, after serving for a while in the army, he turned to literature, producing several light plays. Under Napoleon I he practised with success as an advocate at Bordeaux, and in 1818 he became advocate general of the *cour royale* there. In 1819 he was appointed *procureur général* at Limoges and in 1821 he was returned for Marmande to the chamber of deputies, where he supported the policy of the comte de Villèle. In 1822 he was appointed councillor of state; in 1823 he accompanied the duc d'Angoulême to Spain as civil commissary; in 1824 he was created vicomte and appointed director general of registration. In contact with practical politics, his ultraroyalist views were gradually modified in the direction of the *Doctrinaires* (*q.v.*), and on the fall of Villèle (1827) he was selected by Charles X to carry out the new policy of compromise. On Jan. 4, 1828, he was appointed minister of the interior and, though not bearing the title of president, became the virtual head of the cabinet. He succeeded in passing the act abolishing press censorship and in persuading the king to sign the ordinances of June 16, 1828, on the Jesuits and the minor seminaries. He was exposed to attack from both the extreme left and the extreme right, and when in April 1829 a coalition of these groups defeated him in the chamber, Charles X, who had never believed in Martignac's policy, replaced him by the prince de Polignac (Aug. 1829). His last public appearance was after the July revolution when he defended Polignac in the chamber of peers in Dec. 1830. He died in Paris on April 3, 1832.

Martignac published *Bordeaux au mois de Mars 1815* (1830) and an *Essai historique sur les révolutions d'Espagne et l'intervention française de 1823* (1832).

See E. Daudet, *Le Ministère de M. de Martignac* (1875).

MARTIN, SAINT (c. 330-397), bishop of Tours, missionary and father of monasticism in Gaul, and one of the most revered saints of western Europe, was born at Sabaria in Pannonia (now Szombathely, Hung.) of pagan parents, but became a catechumen at an early age. As a youth he had to serve in the Roman army. His disciple and biographer, Sulpicius Severus, tells the famous story, often depicted in art, of how Martin divided his military cloak with a naked beggar at Amiens. In a dream that night he saw Christ wearing the half cloak, and shortly afterward he received baptism. Later, he asked to be released from the army because "I am Christ's soldier: I am not allowed to fight." When taxed with cowardice he offered to stand in front of the battle line armed only with the sign of the cross, but the immediate surrender of the enemy made this superfluous.

On leaving the army Martin settled at Poitiers, where he was made an exorcist by the bishop St. Hilary. Later he lived in retirement, first at Milan, then on the island of Gallinaria, off Albenga. On Hilary's return from exile in 360 Martin also returned and founded a community of hermits at Ligugé, south of Poitiers, the first monastery in Gaul. Later he founded another, Marmoutier, outside Tours, to which he withdrew whenever possible after becoming bishop of Tours in 372, an office which he accepted unwillingly.

As bishop, Martin was an active missionary in Touraine and beyond. Christianity had scarcely penetrated yet into the country districts, where Martin went round preaching, visiting each of his outlying settlements every year and encouraging monasticism. His fame brought him into contact with the imperial court at Trier, where he took part in a conflict between church and state. He protested to the emperor Maximus, who was being induced to condemn the Spanish heretic Priscillian to death, against the killing of heretics and against civil interference in ecclesiastical matters. Priscillian was nevertheless executed, and Martin's continued protests together with his intercession for Priscillian's followers in-

volved him in difficulties with the Spanish bishops.

Martin died at Candes on Nov. 8, 397. He had acquired a great reputation of working miracles, and was one of the first persons not a martyr to be publicly venerated as a saint. His feast day is Nov. 11, and his popularity in medieval England is attested by calendars and church dedications. See Sulpicius Severus.

See I. Costanza, *La leggenda di San Martino nel medioevo* (1921). (D. Ar.)

MARTIN (MARTINUS), the name of three popes, Martin I, Martin IV and Martin V. In the 13th century the papal chancery misread the names of the two popes Marinus (*q.v.*) as Martin, and as a result of this error Simon of Brion in 1281 assumed the name of Martin IV instead of Martin II.

St. MARTIN I (d. 655), pope from 649 to 655, succeeded Theodore I in June or July 649. He presided over the Lateran synod which condemned the Monothelite heresy. Thereupon by order of the emperor Constans II, Martin was arrested, taken to Constantinople (Sept. 17, 654), publicly humiliated and banished to the Crimea in May 655. He died there the following September. He is honoured as a martyr by the church both in the east (feast day Sept. 16 or the middle of April) and in the west (Nov. 12).

(C. P. L.)

MARTIN IV (Simon of Brie, or Brion) (1210/20–1285), pope from 1281 to 1285, was born between 1210 and 1220 as the scion of a French noble family of Brie. St. Louis IX of France made him a member of his council and, in 1260, chancellor and keeper of the great seal. About a year later the French pope Urban IV elevated Simon to the dignity of cardinal priest of St. Cecilia. He was elected pope on Feb. 22, 1281.

Soon after his coronation at Orvieto on March 23, 1281, Martin IV began to reverse the policy of his great predecessor Nicholas III by restoring Charles of Anjou, king of Sicily, as Roman senator and by favouring his interests in every possible way, even at the expense of the union with the Greeks. Charles apparently convinced the pope that the only guarantee of a permanent union was the conquest of the Byzantine empire by himself, and Martin excommunicated the emperor Michael VIII for lack of sincerity in the cause of the union shortly before the latter's death on Dec. 12, 1282; this led to a new formal break between the churches of Constantinople and Rome under the emperor Andronicus II (1283). After the Sicilian Vespers (*q.v.*) of March 1282 had deprived Charles of Anjou of the island of Sicily, and the Sicilians had chosen Peter III of Aragon as their new ruler, Martin spent the remainder of his pontificate in vain attempts to dislodge him and to reinstate Charles. He excommunicated Peter III, called for a Sicilian "crusade," and declared that Peter had forfeited the kingdom of Aragon, which had been a fief of the Holy See since the 11th century; Philip III of France, Charles of Anjou's nephew, was invited by the pope to take over Aragon for his youngest son, Charles of Valois. However, a Roman uprising against Charles of Anjou cost him his senatorial dignity; a great sea battle between the Aragonese and Angevin fleets resulted in utter defeat of the latter and in the capture of Charles of Anjou's son, the future king Charles II of Naples; while Philip III's campaign in Aragon was likewise to end in disaster in the very year in which the pope died (March 28, 1285) at Perugia. His francophile policy had foreshadowed the Avignonese period of the papacy. Martin IV's successor was the Roman Honorius IV.

(G. B. L.)

MARTIN V (Oddone Colonna) (1368–1431), pope from 1417 to 1431, was born at Genazzano. He was unanimously elected pope on Nov. 11, 1417, in a conclave held during the Council of Constance, which had been called to end the Great Schism (1378–1417). Martin, a mild and gentle man, was at the time a cardinal-subdeacon who had helped organize the Council of Pisa.

As pope he faced enormous difficulties. As soon as the council was over he condemned the widely held conciliar theory which would make the pope subject to a council and forbade any appeal from papal judgment on matters of faith. He returned to Rome, which he found in ruins. He restored some of its churches and fortifications and tried to recover control of the Papal States. He worked to mediate the Hundred Years' War between France and England and to organize crusades against the Hussites in Bohemia.

Although he always had a dread of councils lest they try to revive the conciliar theory, Martin called the Council of Pavia in 1423 as prescribed by the Council of Constance. When a plague struck Pavia he moved the council to Siena. Martin's legates dissolved it (1424) when it dragged on in futile discussion of the conciliar theory. Martin neglected the great opportunity offered by church councils to reform the church; his efforts to meet the crying need for reform were halfhearted and proved ineffective. He died on Feb. 20, 1431, shortly after calling the Council of Basel. See also COUNCIL: *Council of Constance (1414–18)*; CONSTANCE, COUNCIL OF.

MARTIN, ARCHER JOHN PORTER (1910–), British biochemist, was awarded the Nobel prize in chemistry jointly with R. L. M. Synge in 1952 for the invention of partition chromatography. This effected the partition of a substance between two liquids by very simple means instead of by a series of intricate chemical operations and was subsequently so widely applied in chemical, biological and medical research as to constitute almost a new scientific tool. Martin was born in London on March 1, 1910, and was educated at Bedford school and Cambridge university, where he graduated in 1932. He worked in the Dunn Nutritional laboratory on problems relating to vitamin E from 1933 until 1938 when he was engaged with the Wool Industries Research association at Leeds in a study of the felting of wool. In 1946 he became head of the biochemistry division in the research department of Boots Pure Drug Co., Nottingham, and held the post until 1948 when he was appointed to the staff of the Medical Research council, working first at the Lister Institute of Preventive Medicine and then at the National Institute for Medical Research, where he later became head of the division of physical chemistry. In 1959 he became director of Abbotsbury Laboratories, Ltd. He was elected a fellow of the Royal society in 1950, and he received the Berzelius gold medal in 1951.

(D. McK.)

MARTIN, GLENN LUTHER (1886–1955), U.S. aircraft designer, a pioneering airplane inventor, pilot and manufacturer, was born Jan. 17, 1886, at Macksburg, Ia. The family later moved to Liberal, Kan., where his "aircraft" business started when Glenn, aged 8, built kites in his mother's kitchen and sold them to his contemporaries. Later, in Santa Ana, Calif., Martin designed his first powered airplane and leased an abandoned church as his first factory. He became one of the outstanding "barnstormers" in the 1910–14 period, and from that experience developed several successful types of military aircraft. The first Martin bomber appeared in 1918–19, too late for active use in World War I, but its success established Martin as one of the leading military airplane manufacturers of the United States. He built a factory in Cleveland, O., and in 1929 moved his manufacturing facilities to Middle River, Md., near Baltimore. Martin bombers and flying boats played important roles all over the world in World War II. Toward the end of his life Martin took great interest in civic affairs, education (he gave large sums to support the engineering schools in the University of Maryland) and wildlife conservation. He died at Baltimore, Md., Dec. 4, 1955.

(S. P. J.)

MARTIN, (BON LOUIS) HENRI (1810–1883), French historian, author of a famous history of France, was born on Feb. 20, 1810, at St. Quentin. With Paul Lacroix ("le Bibliophile Jacob") he planned a history of France, to consist of excerpts from the chief chroniclers and historians, with original matter filling up gaps in the continuity. His *Histoire de France*, 15 vol. (1833–

36), was the result. This magnum opus, rewritten and further elaborated (4th ed., 16 vol. and index, 1861-65), gained for the author in 1856 the first prize of the Académie Française and in 1869 the grand biennial prize of 20,000 fr. A popular abridgment in seven volumes was published in 1867 (Eng. trans., 1877-82). This, together with the continuation, *Histoire de France depuis 1789 jusqu'à nos jours* (6 vol., 1878-83), gave a complete history of France and superseded J. C. L. de Sismondi's *Histoire des Français*. A staunch republican, Martin sat in the *assemblée nationale* as deputy for Aisne in 1871 and was elected life senator in 1876, but he left no mark as a politician. He died in Paris on Dec. 14, 1883.

MARTIN, HOMER DODGE (1836-1897), U.S. painter, whose works have given him a place at the culmination of American landscape before Impressionism, was born in Albany, N.Y., Oct. 28, 1836. Martin studied briefly with James Hart, and his early work follows the tradition of the Hudson River school. He became a member of the National Academy of Design in 1874 and in 1877 was one of the founders of the Society of American Artists. The sombreness of his pictures prevented them from being sold, and so Martin's wife turned to journalism for support. Sent to England to make magazine illustrations, he later (1882-86) matured his style in France under Barbizon influence. His best works, such as "The Harp of the Winds," "Ontario Sand Dunes" and "Westchester Hills," were done after his return to the United States; their spacious design and rich colour put them on a level with those of Alexander H. Wyant and George Inness. The artist's sight failed a few years before his death at St. Paul, Minn., Feb. 2, 1897. (VL. B.)

MARTIN, LUTHER (c. 1748-1826), U.S. lawyer, a dissenting member of the Constitutional Convention of 1787 who thereafter became an ardent Federalist opposed to the philosophy of Thomas Jefferson. He was born near New Brunswick, N.J., probably in 1748. After graduating from the College of New Jersey (now Princeton university) in 1766, he taught school for a time and in 1771 was admitted to the Virginia bar. Shortly thereafter he settled in Maryland. He served as attorney general of Maryland from 1778 to 1805 and from 1818 to 1822 and during that entire period had an extensive and lucrative practice, private as well as public. He was leading counsel for the defense in two famous state trials of the Jeffersonian era, the impeachment of Justice Samuel Chase (*q.v.*) and the treason trial of Aaron Burr (*q.v.*), and was of counsel in many of the great constitutional cases of the formative years of the United States. His last and most famous was *McCulloch v. Maryland* (1819), involving the right of a state to tax an instrumentality of the federal government (the national bank). Martin, representing the state, abandoned federalism and reverted to his theory of the power of the states for which he had unsuccessfully contended in the Constitutional Convention. He was again unsuccessful.

After his paralysis in 1822 the Maryland legislature passed a unique act requiring each lawyer in the state to pay an annual licence fee to be used by trustees for the financial support of Martin, but he died in poverty on July 10, 1826, at the New York home of his friend Aaron Burr. (A. DM.)

MARTIN, PIERRE ÉMILE (1824-1915), French engineer noted as the inventor of the Siemens-Martin or open-hearth steel process for the manufacture of steel, was born at Bourges, Cher, on Aug. 18, 1824, the son of Émile Martin, owner of the Sireuil ironworks in the Charente. While the chemistry of the steel-making process was already familiar, no means were available for attaining the high temperature required for its operation. On hearing of Sir William Siemens' development of the regenerative furnace about 1863, Martin obtained a licence to build such furnaces, starting with an experimental furnace of one-ton capacity. His steel products exhibited at the Paris exhibition of 1867 gained the exhibition's gold medal award. Nevertheless, his patents were challenged on the ground that he had merely made use of appliances and processes which were already known, and the development of his invention was delayed by prolonged and costly litigation and by the rapid success of the Bessemer process. Martin was reduced to straitened circumstances but, in 1907, the Comité

des Forges de France instituted a fund for his benefit and contributions were received from all the principal steel-making countries. In 1915 he was awarded the Bessemer gold medal of the Iron and Steel Institute, but was unable to attend for the presentation in London. Martin died at Fourchambault, near Nevers, on May 23, 1915. (C. W. D.)

MARTIN, VIOLET FLORENCE (pseudonym MARTIN ROSS) (1862-1915), Irish writer and collaborator with Edith Somerville in a series of novels portraying late 19th-century Irish society, was born at Ross house, County Galway, from which she took her pen name, on June 11, 1862, of an old Irish family.

She spent her childhood in Dublin, and was educated privately and at Alexandra college, Dublin. In 1886 she met her cousin Edith (Enone) Somerville (born at Corfu, May 2, 1858), and thus began a famous literary partnership. Their first book, *An Irish Cousin*, appeared in 1889, and together they published 14 books including *The Real Charlotte* (1894), a powerful novel of Irish life, and *Some Experiences of an Irish R.M.* (1899), a collection of comic short stories which, with its sequels (*Further Experiences of an Irish R.M.*, 1908; *In Mr. Knox's Country*, 1915, etc.), is their most popular work. Although living mainly at Drishane, County Cork, they traveled abroad, but after a hunting accident, Violet Martin was an invalid. Their stories and essays (*Some Irish Yesterdays*, 1906; *Irish Memories*, 1918, etc.) give a sympathetic and witty picture of Irish society. After Violet Martin's death at County Cork, on Dec. 21, 1915, Edith Somerville continued to publish under their pseudonym "Somerville and Ross," claiming that she was still inspired by her cousin. Primarily an artist, she illustrated their books, and also exhibited. She died at Castle Townshend, County Cork, on Oct. 8, 1949.

See G. Cummins, *Dr. E. C. Somerville*, with bibliography (1952).

MARTIN, a name applied to various swallows (family Hirundinidae). The purple martin (*Progne subis*), locally common in Canada and the United States, is the largest of American swallows, about eight inches in length. The male is entirely purplish black; the female and young show considerable gray. This gregarious bird nests in colonies in holes in trees, but will readily inhabit hollow gourds or large apartment-type martin houses provided for the purpose. Its call notes are pleasant, but it has no definite song. The four to six eggs are white; two broods may be reared in a single season. Like most swallows, the purple martin feeds on insects caught in flight and must migrate south in winter. Unfortunately, these welcome summer visitors are intimidated by the more aggressive starlings and house sparrows who often drive them from the garden. Related are the Cuban martin (*P. cryptoleuca*) and the gray-breasted martin (*P. chalybea*) found from central Mexico to central Argentina.

In Europe the house martin (*Delichon urbica*), with its quiet but pleasant song and fluttering flight, nests on buildings and is well known in verse and story. Its presence is thought to add an air of peace and well-being to an estate; thus Shakespeare wrote in *Macbeth*, "Where they [martins] most breed and haunt, I have observed, the air is delicate."

The bank swallow (*Riparia riparia*) is called sand martin in England. The kingbird, an American flycatcher, is sometimes called bee martin. African martins include the genera *Ptyonoprogne* and *Pseudochelidon*. (DN. A.)

MARTIN DU GARD, ROGER (1881-1958), French novelist and dramatist, whose works are not only a vast panoramic survey of the society of his time but also a profound exploration of its meaning, was born at Neuilly-sur-Seine on March 23, 1881, into a professional middle-class family. He studied at the École des Chartes, Paris, and qualified as an archivist and paleographer in 1905. He served with a motor-transport unit throughout World War I and, for a brief period before and after, worked with J. Copeau at the Vieux-Colombier theatre, but he spent the remainder of his life in seclusion, wholly devoted to his writing. He received the Nobel prize for literature in 1937 and died at Bellême, Orne, on Aug. 22, 1958.

His first novel, *Devenir!* (1908), depicted a would-be writer whose talents did not match his ambitions. *Jean Barois* (1913; Eng. trans., 1950) traced the development of an intellectual torn

between the Catholic faith of his childhood and the materialism of maturity; it also described the full impact of the Dreyfus case on French minds. In *Les Thibault* (1922-40; complete Eng. trans., 1939-41), a novel-cycle in eight parts, the protagonists are two middle-class brothers. The younger, Jacques Thibault, rebels against his pharisaical Catholic father and the social order of his day and is killed in the first days of World War I while on a pacifist propaganda mission to the armies in Alsace; Antoine, the elder, is a dedicated doctor who sees no reason to reorganize society; he enlists at the outbreak of war, is gassed and dies in Nov. 1918. The outstanding features of *Les Thibault* are the wide range of human relationships patiently explored, the graphic realism of the sickbed and death scenes and, in the seventh volume, *L'Été 1914*, the dramatic description of Europe's nations being swept into war. The vast scale of the work was inspired by the desire to emulate Tolstoi's *War and Peace*; the corrosive pessimism pervading the strictly impersonal narrative recalls Gustave Flaubert.

Martin du Gard also wrote two peasant farces, *Le Testament du Père Leleu* (1913) and *La Gouffe* (1928), as well as a sombre naturalist drama on homosexuality, *Un Taciturne* (1931). His other works include *Confidence africaine* (1931), a short, sober account of an incestuous liaison; *Vieille France* (1933; Eng. trans., 1954), ferociously bitter sketches of French village life; and *Notes sur André Gide* (1951; Eng. trans., 1953). In 1941 he began work on *Le Journal du colonel de Maumort*, a vast novel which he hoped would prove to be his masterpiece, but it was still unfinished at his death and was still unpublished in 1964.

BIBLIOGRAPHY.—*Oeuvres Complètes de Roger Martin du Gard*, pref-ace by A. Camus, Pléiade ed., 2 vol. (1955); "Hommage à Roger Martin du Gard" in *La Nouvelle Revue française* (Dec. 1958); R. Gibson, *Roger Martin du Gard* (1961); D. Boak, *Roger Martin du Gard* (R. D. D. G.) (1963).

MARTINEAU, HARRIET (1802-1876), English social and historical writer, a prominent public figure of her day, was born on June 12, 1802, in Norwich. Deaf from an early age, and later a victim of heart disease and other illnesses, she was nevertheless undeterred from an active career in which she mingled with the foremost intellectuals of the time. During a serious illness that she underwent from 1839-44, her friends raised an annuity enabling her to buy a small farm, "the Knoll," at Ambleside, which she cultivated until her death there on June 27, 1876.

A popularizer of economics and a propagandist for religious liberalism and for the abolition of slavery, Miss Martineau first gained a large reading public with an extensive series of stories and dialogues illustrating classical economics, chiefly the ideas of Malthus and Ricardo. After a visit to the United States (1834-36) she espoused the then unpopular abolitionist movement and abandoned her belief in a *laissez faire* economy for a more utopian system. A trip to the near east in 1846 led to a study of the evolution of religious beliefs and an increasing skepticism. Her chief historical work, *The History of the Thirty Years' Peace, 1616-1846* (1849), was a widely read popular volume. Her unorthodox views gained her a reputation for radicalism that alienated some of her friends but failed to impede her pursuit of ideas. She became an adherent of the positivist philosophy of Comte, whose *Positive Philosophy* she condensed and freely translated with the approval of the author. Probably this was Miss Martineau's most scholarly work, but she is equally remembered for her candid autobiography, published posthumously in 1877.

In addition to the autobiography, her works include *Illustrations of Political Economy*, 25 vol. (1832-34); *Poor Laws and Paupers Illustrated*, 10 vol. (1833-34); *Illustrations of Taxation*, 5 vol. (1834); *Society in America* (1837); *Retrospect of Western Travel* (1838); *Eastern Life, Past and Present* (1848); *Letters on the Laws of Man's Nature and Development* (1851); *The Positive Philosophy of Auguste Comte, Freely Translated and Condensed* (1853).

See R. K. Webb, *Harriet Martineau: a Radical Victorian* (1960). (H. E. BAR.)

MARTINEAU, JAMES (1805-1900), English philosopher and Unitarian minister, was born at Norwich, Norfolk, of Huguenot ancestry, on April 21, 1805, one of seven children, Harriet

Martineau (q.v.) being one of his sisters. Educated at Norwich grammar school and under the Unitarian Lant Carpenter at Bristol, Gloucestershire, in 1822 he entered Manchester college (then at York) to prepare for the Unitarian ministry.

On leaving college in 1827, Martineau taught for one year with Carpenter at Bristol. His first ministerial appointment was as junior minister at the Eustace Street church, Dublin (1828). He left there in 1832, when on the death of his senior the *regium donum* grant, given by the government to Nonconformist ministers, would have been made to him, and he had conscientious objections to this connection with the state. He was now called to Liverpool, and during his early ministry there he saw reason to depart from the traditional scriptural authority. In his *Rationale of Religious Inquiry* (1836) he laid it down "that the last appeal in all researches into religious truth, must be to the judgment of the human mind," thus anticipating in some measure the famous *Anglican Essays and Reviews* (1860)—notably Benjamin Jowett's essay "On the Interpretation of Scriptures." In 1840 he was appointed professor of mental and moral philosophy at Manchester college, which had returned to Manchester from York. His work as a teacher at the college (and from 1869 as principal) was to continue for 45 years, with a break of 4 years when the college moved to London in 1853. He died in London on Jan. 11, 1900.

The reason why Martineau did not immediately follow the college to London was that his repudiation of scriptural authority had caused misgivings among the old-school Unitarians. Martineau's attempt to establish an alternative to biblical authority in the working of a man's own conscience occupies much of his later work, notably *Types of Ethical Theory* (1885), *A Study of Religion* (1888) and *The Seat of Authority in Religion* (1890), three books that had originated in courses of lectures at the college. In the words of G. Dawes Hicks (see bibliography), the weakness of his position was that:

Having discarded the authority of the Church and of the Thirty-Nine Articles, having relinquished an appeal to the infallibility of the Scriptures or to a miraculous revelation as the ultimate ground of religious trust, it has no alternative but to fall back upon a crude individualism, according to which each man is his own Pope.

A similar criticism was made by Henry Sidgwick. It could still, as in the 18th century, be assumed that an erring conscience could be referred to the Bible for its authority and correction and any position like Martineau's was in difficulties until it could find an adequate alternative court of appeal. It would seem to argue some uneasiness on this score that Martineau twice attempted to come to terms with Spinoza, in his *Types of Ethical Theory* and in *A Study of Spinoza* (1882), whose philosophy offers a solution to this problem.

(H. S. CA.)

MARTINET, a military term (generally used in a disparaging sense) implying a strict disciplinarian or drillmaster. The term originated in the French army about the middle of Louis XIV's reign, and was derived from Jean Martinet, who as lieutenant colonel of the king's regiment of foot and inspector general of infantry, drilled and trained that arm in the model regular army created by Louis and the marquis de Louvois between 1660 and 1670. Martinet seems also to have introduced the copper pontoons with which Louis bridged the Rhine in 1672. He was killed, as a *maréchal de camp*, at the siege of Duisburg in the same year, being accidentally shot by his own artillery while leading the infantry assault. His death, and that of the Swiss captain Soury by the same discharge, gave rise to a bon mot, typical of the polite ingratitude of the age, that Duisburg had cost the king only a martin and a mouse.

The "martin" as a matter of fact shares with the marquis de Vauban and other professional soldiers of Louis XIV the glory of having made the French army the first and best regular army in

Europe. Great nobles, such as the vicomte de Turenne, Prince de Condé and the duke of Luxembourg, led this army and inspired it, but their fame has obscured that of the men who made it manageable and efficient. It was about this time that the soldier of fortune, who joined a regiment with his own arms and equipment and who had learned his trade by varied experience, began to give place to the soldier regularly enlisted as a recruit in permanent regiments and trained by his own officers. The consequence of this happening was the introduction of a uniform, or nearly uniform, system of drill and training. Thus, Martinet was the forerunner of Leopold of Dessau and Frederick William, just as Jean Jacques de Fourilles, the organizer of the cavalry, who was forced into an untimely charge at Seneffe (1674) by a brutal taunt of Condé, and there met his death, was the forerunner of Hans von Zieten and Friedrich von Seydlitz. These men, while differing from the creators of the Prussian army in that they contributed nothing to the tactics of their arms, at least made tactics possible by the thorough drilling and organization they imparted to an army.

MARTÍNEZ CAMPOS, ARSENIO (1831-1900), Spanish soldier and politician, author of the *pronunciamiento* of Sagunto (1874) which restored the Bourbon monarchy in Spain, was born at Segovia on Dec. 14, 1831, and educated as a soldier. He served on the general staff after 1852, took part in the Morocco campaign (1859-60) and in Juan Prim's expedition to Mexico. He fought the Cuban rebels (1869-72) and was promoted brigadier general. When he returned to Spain in 1872, the republican government gave him command of the Catalan brigade which was fighting the Carlists, but he failed because of the indiscipline of his troops. Pres. Nicolás Salmerón put him in charge of the army fighting the cantonalists in Valencia, which he took after a bombardment and then moved against Cartagena and Alicante. He turned against the republic and, at Sagunto, on Dec. 29, 1874, he pronounced for Alfonso XII. In Jan. 1875 he again led the army which was fighting the Carlists in Catalonia and distinguished himself both as a soldier and as a humanitarian who mitigated the brutality of the war. In Navarre he restored law and order. His capture of Baztán (March 1876) earned him the rank of captain general. In Nov. 1876 he arrived in Cuba to put down the rebellion. Again his humane treatment of the enemy won him respect. He forced the rebels to sign the peace of Zanjón (1878). He returned to Spain in 1879 and became, briefly, prime minister. Later, as minister of war under Sagasta, he quelled the republican revolt in Badajoz (Aug. 1883). He was appointed commander of the army in north Africa in Nov. 1893 and negotiated the peace treaty of 1894 with the sultan of Morocco. He was sent to Cuba in 1895 to win over the rebels, but he failed and returned to Spain (1896). He died in Zarauz (Guipúzcoa) on Sept. 23, 1900.

(J. C. J. M.)

MARTÍNEZ DE LA ROSA, FRANCISCO DE PAULA (1787-1862), Spanish statesman and man of letters, whose distinguished career in politics and literature rings strangely hollow in a revolutionary epoch, was born in Granada, March 10, 1787. He was a member of the *Cortes* of Cádiz (1812) and his first prose comedy, *Lo que puede un empleo*, was played there. He was called from exile to be minister in the interregnum (1820-23) and again after further exile in France to be prime minister and creator of a constitution, the *Estatuto Real* (1834), which pleased nobody; but was happier in later years as ambassador (Paris, 1843, 1846, and Rome, 1847) and president of the Ateneo and academy. In literature, similarly, he progressed elegantly but without intimate conflict from Moratinian comedy, Alfierian tragedy and an unexceptional *Arte poética* to the presentation of the first violently romantic drama, *La conjuración de Venecia* (April 23, 1834), a startling amalgam in prose of conflicts, passions, vengeance and cemeteries. His abundant neoclassical poetry reveals a lifelong interest in national history. He died at Madrid, Feb. 7, 1862.

MARTÍNEZ RUIZ, JOSÉ: see AZORÍN.

MARTÍNEZ SIERRA, GREGORIO (1881-1947), one of the outstanding Spanish dramatists and producers of the 20th century, was born at Madrid on May 6, 1881. He published his first work, *El Poema del Trabajo*, at the age of 17, and although his

true vocation was the theatre, he first won recognition as a poet and critic with *La Tristeza del Quijote* (1905) and *Tú eres la Paz* (1906). His best plays were *Canción de Cuna* (1911; *Cradle Song*), *Primavera en otoño* (1911; *The Romantic Young Lady*), *El Reino de Dios* (1916; *The Kingdom of God*) and *Los Pastores* (1913; *The Two Shepherds*). These owed much of their success in London and New York to the translations by Harley Granville-Barker. His *Un Teatro de arte en España* (1926) describes his work at the Teatro Eslava, Madrid, of which he was director from 1917 to 1928. He died at Madrid on Oct. 1, 1947. (W. F. Sz.)

MARTÍNEZ ZUVIRÍA, GUSTAVO: see WAST, HUGO.
MARTINI, FRANCESCO DI GIORGIO: see FRANCESCO DI GIORGIO.

MARTINI, GIOVANNI BATTISTA (called PADRE MARTINI) (1706-1784), Italian composer, theorist and teacher was born at Bologna on April 24, 1706. He learned the rudiments of music from his father, a violinist, and later studied singing, harpsichord and organ with Luc' Antonio Predieri and counterpoint with Antonio Ricieri. On Sept. 11, 1722, he was ordained, and in 1725 he was appointed *maestro di cappella* of the church of S. Francesco at Bologna. He opened a school of music, and the fame of his teaching made Bologna a place of pilgrimage for musicians from all countries. Among his pupils were Giuseppe Sarti and J. C. Bach. He died at Bologna on Oct. 4, 1784.

Martini was a zealous collector of musical literature; his library, which Charles Burney estimated at 17,000 volumes, passed at his death to the Imperial library at Vienna and to the city of Bologna. He was a prolific composer of sacred and secular music; his works include the *Litanie* (1734), 12 *Sonate d'intavolatura* (1741), 6 *Sonate per l'organo ed il cembalo* (1747) and the *Duetti da camera* (1763). His most important literary works are the *Storia della musica* (1757-81), unfortunately never completed, and the *Saggio di contrappunto* (1774-75). (Cs. Ch.)

MARTINI (DI MARTINO), SIMONE (c. 1284-1344), Italian painter, incorrectly called Simone Memmi by Giorgio Vasari, was an early and important exponent of Gothic painting who did more than any other artist to spread the influence of Sienese painting. He was very possibly a pupil of Duccio di Buoninsegna (q.v.), from whom he inherited his love of harmonious, pure colours and most of his early figure types. To these he added a gracefulness of line and delicacy of interpretation which were inspired by French Gothic works, which the young artist studied in Italy. He carried to perfection the decorative line of the Gothic style, and he subordinated volume to the persuasive rhythm of this line, giving his figures a transcendental beauty and grace.

Simone's earliest documented work is the large fresco in the Sala del Mappamondo of the Palazzo Pubblico, Siena, representing the "Madonna Enthroned with the Child, Angels, and Saints." This painting, signed and dated 1315, but retouched by Simone himself in 1321, is a free version of the main representation in Duccio's "Maestà" of 1308-11. However, the abstract character and lack of setting of the earlier work has given way to concrete concepts: Simone's Virgin, crowned and splendidly attired, is a Gothic queen who holds court under a Gothic canopy. About 1317 the artist painted in Naples the highly spiritual altarpiece "St. Louis of Toulouse Crowning His Brother, King Robert of Anjou," now in the Museo di Capodimonte in that city. Two or three years later he composed for Sta. Caterina, Pisa, a colouristically magnificent Madonna polptych, which is now in the Museo Nazionale, Pisa. Perhaps in the middle of the 1320's he began the ten scenes, full of chivalrous ideals, from the life of St. Martin of Tours in this saint's chapel in the lower church of S. Fran-

BY SIMONE MARTINI. IN THE
CHURCH OF S. FRANCESCO, ASSISI

cesco, Assisi. More down to earth is the equestrian portrait of 1328 in the Palazzo Pubblico representing Guidoriccio da Foligno, general of the Sienese republic. On the other hand, deliberately unreal is the "Annunciation" triptych, painted for the Cathedral of Siena, but now in the Uffizi gallery, Florence. Simone signed this work in 1333 with his brother-in-law, the Sienese painter Lippo Memmi, an associate for many years. The exquisite rhythm of the lines and dematerialized forms of Gabriel and Mary in the central part of the "Annunciation" led many artists to imitation, but none of them achieved as vibrant contours and as spirited forms as did Simone in this great masterpiece.

In 1339 the painter settled at the papal court in Avignon, where he remained until his death in 1344, and where he made the acquaintance of Petrarch. He executed for the poet a portrait of his beloved Laura, as is known from two of Petrarch's sonnets, in which Simone is eulogized.

Simone was the most important Sienese painter after Duccio. His influence in Siena was great in the 14th century and considerable in the 15th. His art was imitated by local painters in Naples, Pisa, Orvieto, Assisi, and Avignon.

BIBLIOGRAPHY.—Giovanni Paccagnini, *Simone Martini* (1955) with a comprehensive bibliography. Useful discussions of Simone's life and art in English are to be found in Raimond van Marle, *The Development of the Italian Schools of Painting*, vol. 2 (1924); and in Curt H. Weigelt, *Sienese Painting of the Trecento* (1930). For Petrarch's references to Simone's portrait of Laura consult Francesco Petrarca, *Le Rime* (1929), sonnets LVIII and LIX, no. LXXVII and LXXVIII. (G. M. Cr.)

MARTINIQUE (LA MARTINIQUE), an island and French overseas *département* of the Antilles, is located in the eastern Caribbean between the British islands of Dominica and St. Lucia.

Relief and Geology.—The island, 431 sq.mi. in area, has mountainous topography typical of the inner, volcanic arc of the Lesser Antilles, at the centre of which it lies. In the north the gently sloping cone of Mt. Pelée, an active volcano, rises to 4,554 ft.; the centre is dominated by the older volcanic massif of Pitons du Carbet (3,911 ft.) and to the south, beyond the Lamentin Plain, low hills rise to between 1,000 and 2,000 ft.

The rocks of the centre and south are mainly Miocene volcanics (andesite, labradorite, and dacite) which, in the extreme south-east, are interbedded with tuffs and limestones of the Oligocene period. The Mt. Pelée massif is made up of recent volcanic ashes and lavas, the product of successive eruptions. The most devastating of these occurred on May 8, 1902, when the town of St. Pierre was destroyed and about 30,000 people were killed. Ravines score the flanks of Mt. Pelée and the steeper, western slopes of the Pitons du Carbet. The remainder of the island is drained by the numerous streams and by several larger rivers which flow to the west coast. The northern coasts are steep, cliffed and relatively smooth but to the south of the Pitons du Carbet the coastline becomes lower and more indented with the large bays of Fort-de-France and Le Marin on the west and many headlands, coves, and coral reefs on the east.

Climate.—The temperature on Martinique remains equable throughout the year. In the lowlands it varies from a maximum monthly mean of 28° C (83° F) in June to a minimum of 25° C (77° F) in January, while in the mountains somewhat lower temperatures prevail. Most of the island receives between 60 and 100 in. of rainfall annually. The rainy season normally lasts from July to November and occasional hurricanes also occur during that period. The months of January to April are usually dry.

Vegetation and Animal Life.—Tropical rain forest clothed the mountains of Martinique before European settlement began, but it has since been extensively cleared for agriculture and no virgin forest remains. In the lower and drier south, scrub woodlands occupy uncultivated lands while the slopes of Mt. Pelée and Pitons du Carbet support more luxuriant secondary forest. The variety of animals native to Martinique is small and has been further reduced by man, through clearance of the forest, hunting and the introduction of alien animals. The Indian mongoose was introduced about 1880, with the hope of controlling the spread of rats and exterminating the deadly fer-de-lance (*Bothrops atrox*), but it failed to eradicate this poisonous snake and instead brought

PATRICIA CAULFIELD FROM PHOTO RESEARCHERS

MARKET IN FORT-DE-FRANCE, CAPITAL OF MARTINIQUE

about the extinction of several species of harmless reptiles, birds and mammals.

History.—When Martinique was discovered in 1502 by Columbus on his fourth voyage it was occupied by Carib Indians who had recently migrated from South America and had driven out a pre-existing population of Arawak Indians. The Spaniards did not settle the island and it remained unoccupied by Europeans until 1635, when Pierre Belain, sieur d'Esnambuc, established the first colony for the French Compagnie des Iles d'Amérique. In 1637 Dyel du Parquet, D'Esnambuc's nephew, became captain general of the colony and later purchased the seigneurie of the island from the company. In 1674 it passed to the French crown. Life on the island in the 17th century is vividly described in the writings of J. B. du Tertre and J. B. Labat.

In the latter half of the 17th century Martinique was repeatedly attacked by the English and Dutch but it was not captured until 1762, when the English held it for one year. It was again in British hands from 1794 to 1802 and from 1809 to 1814, after which it was permanently restored to France. In 1848 slavery was abolished and about 74,000 slaves were freed. Martinique became a *département* of France in 1946.

Population.—In 1658 the settlers on Martinique numbered about 5,000. Warfare and assimilation gradually eliminated the Caribs, and the racial mixture of the population was increased by the large-scale importation of Negro slaves. Today all degrees of racial commixture exist, though Negroes predominate. In 1954 the total population including outlying dependencies was 239,130 and by 1961 it had risen to 292,062, of whom about 75,000 lived in the capital city, Fort-de-France; other major towns are

Le Lamentin on the plain east of Fort-de-France and La Trinité, Le Robert and Le François on the east coast. The density of the population is high—677 per square mile—and because of its rapid increase, together with the progressive mechanization of sugar production, the island faces acute overpopulation.

Administration.—Martinique, an overseas *département* of France, is divided into two *arrondissements* comprising 34 communes, each administered by an elected municipal council. Executive government is conducted by a prefect and other appointed officials and legislative authority is vested in a general council of 36 members elected by popular vote. Martinique is represented in the French National Assembly by three deputies and in the Senate by two senators. There are more than 250 primary and also 4 secondary schools providing free public education, as well as a technical college, a law school and several private schools. Scholarships for higher education in France are held by about 450 students.

Economy.—The economy of Martinique is overwhelmingly agricultural. At first cotton and tobacco were the principal crops but in 1650 sugar planting began and sugar has since remained the dominant crop. The principal exports of the island are bananas, sugar, and rum. Nearly all external trade is with France; imports consist primarily of foodstuffs, petroleum products, and textiles.

Martinique is served by French, U.S., Canadian, and British shipping and airlines which use the harbour at Fort-de-France and the airport at Le Lamentin. A majority of the visitors arrive by air. Local communication is by small coastal steamers and by automobiles and buses on about 400 mi. of national and district roads.

MARTINUZZI, GYÖRGY (properly JURAJ UTISENOVIC) (1482–1551), whose political achievements in Hungary and in Transylvania finally won him elevation to the cardinalate, but who was known during most of his career simply as FRATER (Brother) GYÖRGY, was born at Kamieć in Croatia, the son of Grgur Utiesenovic and a Venetian lady of the patrician family of Martinuzzi. In his youth he was attached to the court of John (János) Corvinus; and subsequently he saw military service under John Zápolya. Tiring of this life, he entered the Paulist order in his 28th year, becoming the prior of their Csestochowa monastery in Poland. In 1528, however, his old patron John Zápolya, who had been elected king of Hungary but had been put to flight by his rival Ferdinand of Austria, sent him on a diplomatic mission to Hungary. It was due to his efforts that John recovered Buda (1529), and henceforth Martinuzzi became his treasurer and chief counselor.

In 1534 Martinuzzi became bishop of Nagyvárad (Oradea Mare) in Transylvania; and in 1538 he concluded with Ferdinand the peace of Nagyvárad, which left Zápolya with the royal title and most of Hungary. On Zápolya's death in 1540 Martinuzzi acted as guardian and regent for his infant son John Sigismund. For the latter he concluded the treaty of Gyula with the Ottoman sultan, Suleiman I (Dec. 29, 1541), which made Transylvania an independent principality under Turkish suzerainty. For a time Martinuzzi kept Transylvania neutral and on friendly terms with both Austria and Turkey. Though John Sigismund's mother, Isabella, who hated Martinuzzi, contrived against him with the hospodars of Moldavia and Walachia and the Turks in 1550, Martinuzzi defeated all his enemies and concluded an agreement, confirmed by the diet of Kolozsvár (Cluj) in 1551, whereby Isabella renounced her rights over Transylvania, in her son's name, to Ferdinand.

Martinuzzi retained the governorship of Transylvania and was subsequently consecrated cardinal and archbishop of Esztergom. Thus Hungary was once more reunited. Ferdinand, however, was unable to defend the country against the Turks, so that Martinuzzi had to resume payment of tribute to the Porte in Dec. 1551. Then, suspecting the cardinal's loyalty, Ferdinand had him assassinated at Alvincz (Dec. 17, 1551). Assuming responsibility for the murder, Ferdinand sent an accusation of treason against Martinuzzi

in 87 articles to Pope Julius III, who after long hesitation and the testimony of 116 witnesses, exonerated Ferdinand of blame. There is an edition of Martinuzzi's letters from 1535 to 1551 by A. Károlyi (1881).

See O. M. Utiesenović, *Lebensgeschichte des Cardinals Georg Utiesenović* (1881). (T. K.)

MARTYN, HENRY (1781–1812), English missionary to India, was born on Feb. 18, 1781, at Truro, Cornwall. He was educated at Truro grammar school and St. John's college, Cambridge, of which he became fellow in 1802. He obtained a chaplaincy under the East India company and left for India in 1805. Martyn translated the whole of the New Testament into Urdu, and into Persian twice, and the Psalms into Persian. Ordered to take a sea voyage for reasons of health, he went to Persia to correct his Persian New Testament. He set out from Bombay in Jan. 1811 for Bushire. After an exhausting journey from the coast he reached Shiraz and was soon plunged into discussion with disputants of all classes. Having made an unsuccessful journey to Tabriz to present the shah with his translation of the New Testament, he fell ill with fever and had to seek a change of climate. On Sept. 12, 1812, he started a journey across Asia Minor with two Armenian servants. Although the plague was raging at Tokat, he was compelled by prostration to stop there. On Oct. 6, he died. His New Testament was later presented to the shah by the English ambassador, printed and put into circulation.

See *his Journals and Letters* (1857), ed. by Samuel Wilberforce; C. E. Padwick, *Henry Martyn, Confessor of the Faith* (1953).

MARTYN, JOHN (1699–1768), English botanist, author and translator of Virgil, was born in London on Sept. 12, 1699. From 1733 to 1761 he was professor of botany at Cambridge and from 1730 to 1752 a physician at Chelsea, where he died on Jan. 29, 1768.

His reputation rests chiefly upon his translations, with critical notes, of the Georgics (1741) and Bucolics (1749) of Virgil and his *Historia plantarum rariorum* (1728–37), describing and illustrating in colour noteworthy plants. The work was discontinued after five parts were published.

See G. C. Gorham, *Memoirs of John Martyn and Thomas Martyn* (1830). (J. W. Tr.)

MARTYR. The original meaning of the Greek word *martys* was "witness"; in this sense it is often used in the New Testament. Since the most striking witness which Christians could bear to their faith was to die rather than deny it, the word soon began to be used in reference to one who was not only a witness but specifically a martyr. This usage is present, at least implicitly, in Acts xxii, 20 and Rev. ii, 13.

Early Christian Martyrs.—The first Christian martyrs were St. Stephen (Acts vi, 8–vii, 60) and St. James (Acts xii, 2). Of the apostles the most important martyrs were SS. Peter and Paul, both put to death at Rome (I Clement v). Clement of Rome describes them as God's athletes, contending for the heavenly prize, and mentions a "great multitude" executed at the same time (probably under Nero; cf. Tacitus, *Ann.*, xv, 44). Early in the 2nd century Ignatius of Antioch described his own prospective martyrdom as a way of "attaining to God" and urged the Roman Christians not to make any effort to have him spared. In the sporadic persecutions of the first two centuries martyrdoms were not especially frequent, but the martyrs were highly regarded by Christians (the emperor Marcus Aurelius viewed their constancy as theatrical). The earliest authentic "Acts of Martyrs" surviving are those of Justin at Rome c. 165, of Polycarp at Smyrna c. 167, of about 50 Christians at Lyons and Vienne (Gaul) in 177 and of a few at Scillium in Africa in 180. (These Acts of the Scillitan Martyrs are of special interest as being the earliest documents of the church of Africa and the earliest specimen of Christian Latin.) In addition, from the Roman side there are letters exchanged by Pliny the Younger, legate in Bithynia-Pontus, and the emperor Trajan in the year 112 (Pliny, *Ep.*, x, 96–97). From all these accounts something of the procedure involved can be made out. The government's position was not entirely clear. Were Christians to be condemned as Christians because of specific criminal charges or because of crimes inherent in the profession of

Christianity? In any event, they were ordered to prove their abandonment of Christianity by offering sacrifices to the Roman gods; when they refused to do so, they were executed. Veneration of a martyr's relics is first attested in the *Martyrdom of Polycarp*.

With the passage of time and with a fresh emphasis on martyrdom (often regarded as a substitute for baptism) in the persecutions under Decius (A.D. 250) and Diocletian (A.D. 303–311), the authentic acts of the early martyrs were often replaced by legendary accounts (for instance, none of the versions of the death of Ignatius is genuine). Though doubts about these new narratives had arisen earlier, it was not until the late 19th century that the study of martyr acts was placed on a secure foundation, above all by the writings of the Bollandist Hippolyte Delehaye (*q.v.*; see also BOLLANDISTS), who applied literary and historical criticism to these acts with significant success. After his time the study was advanced by the work of Herbert Musurillo, who carefully examined the papyrus fragments that record the difficulties of Alexandrian "martyrs" before various Roman emperors. These accounts do not provide prototypes of the martyr acts (closer parallels are found in such Hellenistic Jewish writings as IV Maccabees), but they reflect the kind of situation out of which martyr acts arose. (See also SAINT.) (R. McQ. G.)

Christian Martyrologies.—A martyrology is an official catalogue or calendar of martyrs and saints arranged in the order of their feast days; in the Greek Church the equivalent is called a *synaxarion*. Simple martyrologies or calendars, which consist of an enumeration of martyrs and saints according to the days of the month and year, are to be distinguished from historical martyrologies, which add hagiographical details. Martyrologies are also classed as local (giving the feasts of a particular church or group of churches) and general (compiled by combining local martyrologies). The name martyrology points to the fact that in the earliest Christian centuries martyrs alone figured in these lists. Later, mention was made of bishops, the dedication of churches, founders of churches, confessors, etc. Among early calendars which have survived is the Philocalian, that of the Roman Church in 354.

The development of the calendar into a martyrology was a natural process. The most ancient surviving are the Syrian martyrology (*Breviarium Syriacum*, A.D. 411) and the Hieronymian of the middle of the 5th century. The latter purports to be the work of St. Jerome, a claim rejected by critics. The 8th and 9th centuries saw the development of historical martyrologies in England, at Lyons in France, and elsewhere. The martyrology of Usuard, a Benedictine monk, was widely used.

The Roman martyrology (*Martyrologium Romanum*), the official martyrology of the Roman Catholic Church, compiled at Rome and issued by Gregory XIII in 1584, is based on the historical martyrologies, some Greek menologies, the Dialogues of St. Gregory the Great, and the calendars of many churches, particularly Italian churches. It has been frequently re-edited and improved but critically still leaves much to be desired. (See also HAGIOLOGY.) (E. A. R.)

Jewish Martyrs and Martyrologies.—The ideal of martyrdom is deeply imbedded in Jewish consciousness. It begins with Abraham, who according to legend was cast into a lime kiln and saved from the fire by divine grace. The tradition was continued by Isaac, who consented to be sacrificed by his father. Many Jewish commentators interpreted Isaiah's vision of the "Suffering Servant" as referring to the destiny of the people Israel (Isa. liii). The Book of Daniel made the ideology of martyrdom explicit and popular. Readiness for martyrdom became a collective Jewish ideal during the Antiochene persecution and the Maccabean rebellion of the 2nd century B.C. The best-known episode was that of the mother and her seven sons (II Macc. vii). The readiness of even the common peasants to die for the "sanctification of the Name" was demonstrated when Petronius, the Roman governor of Syria, encountered a numberless mass gathered in the valley of Acco, barring his way to the Temple (A.D. 40). Martyrdom was preferred to the desecration of the Sabbath by the early *Hasidim*. In Hadrian's time, pious Jews risked death to circumcise their children, and Rabbi Akiba embraced martyrdom to assert the right

to teach the Law publicly. The Talmud cites the majority opinion that one should prefer martyrdom to three transgressions—idolatry, sexual immorality and murder (*Sanhedrin* 74a).

The Midrash on Lam. ii, 2 contains what is probably the oldest Jewish martyrology, the list of the "Ten Martyrs" under Trajan and Hadrian. It was repeated in later *midrashim* and formed the theme of several liturgical elegies, including the *Eleh Ezkerah*, included in the Yom Kippur service. During the European persecutions of the later middle ages, chronological registers of martyrs were drawn up for use in synagogue commemorative services. In 1296 Isaac ben Samuel of Meiningen began to collect these in the *Memorbuch* of Nürnberg, published by S. Salfeld in 1898; it covers the years 1096–1349.

In a sense, Jewish life was a nearly continuous training in martyrdom. Martyrs are honoured as *kedoshim* ("the holy ones"). Rabbi Shneur Zalman of Ladi, founder of the HaBaD Hasidism, considered the spirit of martyrdom (*mesirut nefesh*) to be the distinguishing quality of the Jewish people. (J. B. A.)

Miller*, pp. 29–55 (1938).

MARVEL, IK: see MITCHELL, DONALD GRANT.

MARVELL, ANDREW (1621–1678), English poet, whose political reputation overshadowed appreciation of his unique gifts as a poet until the 20th century, was born on March 31, 1621, at Winestead, Yorkshire, where his father was rector. The latter moved in 1624 to become master of the Charterhouse, an almshouse (with a garden) just outside the city wall of Hull, and preacher (not incumbent) at the parish church. The boy attended Hull grammar school, and in his 13th year (like other boys from schools which did not carry education very far) proceeded to the university. He was a sizar at Trinity college, Cambridge, from 1633 to 1638, when he became a scholar, and took his B.A. in 1639. In Jan. 1641 his father was drowned when crossing the Humber, which may account for Marvell's departure from the university. Otherwise he would have proceeded M.A. and, being a first-rate scholar without great worldly ambition, would probably have enjoyed a distinguished academic career. One Greek and one Latin poem survive from his university days and also a well-authenticated story that he was temporarily led away by the Jesuits.

He had his living to earn. His brother-in-law Edmund Pople, a Hull merchant, probably took him into his office, but for four years, almost certainly 1642–46, he traveled on the continent, to Holland, France, Italy and Spain, thus missing the Civil War. He can only have done this as a tutor, almost certainly to one of the Skinner family of which Milton's friend Cyriack is the best

known. At Rome he met Richard Flecknoe (*q.v.*), whom he satirized in a style reminiscent of both Horace and Donne. Back in England he may have contemplated a literary career in royalist circles, as the poems on Richard Lovelace, Lord Hastings and Lord Francis Villiers, younger brother of the 2nd duke of Buckingham, suggest; but Yorkshire drew him, and about 1651–52 he was tutor at Nun Appleton to Lord Fairfax's daughter Mary. Perhaps his political views were changing, but in neither religion nor politics was he ever a bigoted partisan. A moderate man, he was more influenced by persons than principles. His one firm persuasion was

English patriotism. Now, though he admired Charles I's demeanour on the scaffold and though in 1651 he wrote scathingly about the Puritan historian Tom May, Oliver Cromwell's strength of character won him over ("An Horatian Ode upon Cromwell's Return From Ireland" 1650). In 1653 Milton made an abortive attempt to get him appointed his assistant in the Latin secretaryship. Instead he became tutor to Cromwell's ward William Dutton from 1653 to 1657, at first at Windsor in the house of John Oxenbridge who had been to Bermuda (*cf.* "Bermudas"), later at Saumur, France, where there was a noted Protestant academy. In 1657 Marvell was himself appointed Latin secretary (*i.e.*, foreign secretary) under John Thurloe, the secretary of state, an office he held till the Restoration. Though poems on "The First Anniversary" (1655) and "On the Death of O.C." show his continued and growing admiration of Cromwell, his role was that of the civil servant, not the politician. His political career began with his election as M.P. for Hull in Richard Cromwell's parliament (1659). He was re-elected in 1660 and 1661 and was a house of commons man for the rest of his life. Dissatisfaction with Clarendon's government, especially the disastrous conduct of the Dutch War of 1664-67, appears in the long, witty and still most readable "Last Instructions to a Painter," written in 1667 but, like all but one of his political satires, not published till after the Revolution. In the next decade alarm about the king's intentions produced the anonymous *An Account of the Growth of Popery and Arbitrary Government in England* (1677), purporting to have been printed at Amsterdam. Traces survive of his close touch with the leaders of the Country party, but the long series of newsletters to the Hull corporation is concerned mostly with bare facts. The corporation paid him 6s. 8d. for each day's parliamentary attendance and also sent presents in kind. The only long break in attendance was in 1663-65 when he went as secretary on an embassy to Russia.

In 1678 Marvell, who seems to have been unmarried, had an attack of fever at his London lodgings and died on Aug. 18 through medical incompetence. He had in his charge £500 belonging to two Hull friends who hoped thereby to save something from their bankruptcy. They arranged with his housekeeper-servant, Mary Palmer, to claim that she was his widow and entitled to his property. Marvell's Hull relations took out letters of administration for his property there, but Mary Palmer, finding his manuscript poems, had them published as "of my late dear Husband" (*Miscellaneous Poems by Andrew Marvell, Esq.*, 1681): the object was probably not to make money by poems quite out of fashion but to bolster up the claim to widowhood. Otherwise most of the poems might have been lost for ever, or, like Thomas Traherne's, accidentally discovered two centuries later.

The 1681 volume was accurately described as miscellaneous. Its 58 items even include a letter and four prose epitaphs. Whatever poems, early or late, have not survived, the variety of Mary Palmer's haul suggests that it included what Marvell thought his best. There are, for example, a few dialogues, moral, pastoral or pastoral-moral; a few poems full of "metaphysical" conceits ("The Definition of Love" is as intellectual as anything of Donne's, and "To His Coy Mistress" sets playfulness against a sternly sublime background); two characteristically 17th-century "weeper" poems ("Eyes and Tears," "Mourning"); one narrative ("The Nymph Complaining for the Death of Her Faun") in a unique way reminiscent of the Civil War; one meditative description of a portrait ("The Picture of little T.C."); two personal satires ("Flecknoe" and "Tom May's Death"), one without and one with venom. The group of Mower poems probably belongs to the Nun Appleton period, as the two local poems ("Upon the Hill and Grove at Bill-borow" and "Upon Appleton House") and "To Doctor Witty" certainly do. The moment of deepest experience in "Upon Appleton House" is similar to that in "The Garden" ("My Soul into the boughs does glide"), which on the evidence of its last stanza can also be ascribed to the two years of bliss with Fairfax: but a poet's maturest expression is based on repeated experiences, and it is not fanciful to trace to the Charterhouse garden the beginning of Marvell as the garden-loving poet.

Other poems of the 1650s can be dated by their subject-matter.

"An Horatian Ode" (Horatian, *i.e.*, not Pindaric), the two other Cromwell poems and "Bermudas" have been mentioned above. *The Character of Holland*, a satire of more than Hudibrastic wit, was occasioned by the Dutch War of 1652-54; "On a Victory Obtained by Blake" (1657) by the Spanish War; "Two Songs" by the marriage of Cromwell's daughter Mary (1657). Latin poems for diplomatic occasions indicate the aspirant to scholarly government service. Much later (1674) is the poem prefixed to the second edition of Milton's *Paradise Lost*. It occurs, oddly, near the middle of the volume. The arrangement of the contents cannot have been Marvell's but, with exceptions, it is intelligent and systematic, and is presumably the publisher's. He misplaced "Bermudas" through ignorance, and the pastoral "Dialogue Between Thyrsis and Dorinda" perhaps because it was a late find while the book was in the press. Though not a great poem, it is interesting: first, because in part at least it is known to have been in existence in 1643; secondly, because it was published (without the author's name) as words to music in 1659. At the last moment the publisher of the folio took fright about the three English Cromwell poems ("An Horatian Ode," "The First Anniversary," "Upon the Death of O.C.") and cut them out.

Though it cannot be proved that none of the *Miscellaneous Poems* (except that to Milton and Latin suggestions for an inscription on the Louvre) were written after the Restoration, it is improbable both for stylistic reasons and because it is known that Marvell became more and more absorbed by politics. He did from 1667 onward write anonymous verse satires, but, with exceptions, it is not easy to be sure which of those popularly (or conveniently) ascribed to him after his death in 1678 were really his. They circulated in manuscript and were printed after the Revolution in *Poems on Affairs of State* (1689-1716). His acknowledged success was in prose, *The Rehearsal Transposed* (1672-73). This was a witty best-seller and laughter-causer of the day, an attack on an ecclesiastico-political adversary, Samuel Parker, later James II's bishop of Oxford and president of Magdalen college.

In the same vein as *The Rehearsal Transposed* was *Mr. Smirke: or the Divine in Mode* (1676; again a title taken from a current play). Marvell at this time developed an interest in the origins of the early church which produced *A Short Historical Essay Touching General Councils, Creeds, and Impositions in Matters of Religion* (1680), a pamphlet cutting the ground from the usual Protestant view of the first four centuries and well on the way to the deism of his nephew William Popple, author of *A Rational Catechism* (1687).

Achievement and Reputation.—While Marvell's controversial prose is now interesting only to specialists, and while his verse satire is far inferior to Dryden's and no better than that of dozens of his contemporaries, his small but exceptionally varied collection of miscellaneous poetry has continued to rise steadily in the estimation of general readers ever since Charles Lamb may be said to have discovered it. After Donne, perhaps even together with Donne, he is the finest of those many fine amateur poets of the earlier 17th century who wrote, not for publication, but for their own pleasure and that of their friends, and whose poetry reflects so much of what is most attractive in the culture and society in and out of which it was written. While no poetry could well be more original, could more unmistakably reveal the hand of its author, than Marvell's, it is at the same time continuously dependent on the example and stimulation of predecessors and contemporaries. This is one of the great differences between Marvell and Donne; for while Donne seems to have resolved to write in a manner in which no English poet had ever written before, Marvell, it might almost be said, was willing to accept, to exploit and to re-combine anything that had ever made poetry enjoyable. He is the only great metaphysical poet who did not break with the Elizabethan past, and who combines something of Donne's dialectic and ingenuity with a pastoral, pictorial and descriptive content which may be regarded as a development both of Elizabethan pastoralism and of those "catalogues of delights" (they seem to begin with Theocritus' description, imitated by Ovid, of Polyphemus' wooing of Galatea) of which Marlowe's *Passionate Shepherd* inspired so many imitations and of which

even Milton's *L'Allegro* and *Il Penseroso* may be regarded as examples. Marvell, in fact, is the most eclectic of all 17th-century poets, and his originality consists very largely in the beauty and piquancy of his various combinations of old and new.

In spite of two 18th-century editions no one before Charles Lamb took any real interest in Marvell's poetry. He was revered as an incorruptible Whig, a republican of complete integrity. Wordsworth linked him with Algernon Sidney and James Harrington. In the 19th century he was republished and anthologized, but not till the 20th was he fully recognized as nature-mystic, meditative patriot, wit of great depth and superb master of the octosyllabic couplet.

BIBLIOGRAPHY.—*The Works of Andrew Marvell* were ed. by T. Cooke, 2 vol. (1726) and E. Thompson, 3 vol. (1776). Their rediscovery in the late 19th century was marked by A. B. Grosart's *The Complete Works in Prose and Verse of Andrew Marvell*, 4 vol. (1872–75). *Poems and Letters* were ed. by H. M. Margoliouth, 2 vol. (1927; 2nd ed., 1953); *Poems: Printed from the Unique Copy in the British Museum, With Some Other Poems*, were ed. by H. Macdonald (1952); and *Selected Poetry and Prose* was ed. by D. Davison (1952). See also P. Legouis, *André Marvell, Poète, Puritain, Patriote* (1928); M. C. Bradbrook and M. G. Lloyd Thomas, *Andrew Marvell* (1940), with a summary of the evidence about Mary Palmer. (H. M. MA.)

MARX, JOSEPH (1882–1964), Austrian composer, known for his songs in an impressionist style, was born at Graz on May 11, 1882. He studied music and the history of art at Graz and from 1911 onward wrote about 150 songs on poems of Albert Giraud ("Valse de Chopin" from Pierrot Lunaire, set also by A. Schoenberg), Paul Heyse, T. Löngen and others. They show the influence of Hugo Wolf, whose songs he orchestrated, of Scriabin and of the French impressionist composers. In 1914 he was appointed professor of the state academy of music at Vienna, becoming director in 1922. In 1924 he was director of the Hochschule für Musik in Vienna. He was music critic of the *Neues Wiener Journal* (1931–38) and later of the *Wiener Zeitung*. Some of his essays were published in book form under the title *Betrachtungen eines romantischen Realisten* (1947). He also wrote symphonic and chamber works. Marx died in Graz on Sept. 3, 1964.

See A. Liess, *Joseph Marx: Leben und Werk* (1943).

MARX, KARL HEINRICH (1818–1883), German philosopher of history and the most important figure in the history of socialist thinking, was born, May 5, 1818, of Jewish parents in the town of Trèves (Trier) in Rhenish Prussia. In 1824 his father, a lawyer with a keen interest in philosophy, embraced Christianity and all members of the family were baptized as Protestants. During his student days at the universities of Bonn and Berlin, Marx studied history and was strongly influenced by the works of Georg Wilhelm Friedrich Hegel (*q.v.*), an influence that always remained one of the most important elements in his thinking. In 1841 he received a doctor's degree from the University of Jena. His liberal political views led him to consider journalism as a career and in 1842 he became an editor of the *Rheinische Zeitung* in Cologne. The following year he married Jenny von Westphalen, close friend of his boyhood and daughter of a high government official. It was a marriage of deep love that withstood the vicissitudes of all the subsequent years.

Shortly after his marriage, Marx's newspaper was suppressed and he emigrated to Paris with his wife. There he became acquainted with French socialist writers and established his lifelong friendship with Friedrich Engels. Both these influences led Marx to become a socialist.

In 1847, at a new place of exile in Brussels, Marx wrote a reply to P. J. Proudhon's book *Philosophie de la misère* ("Philosophy of Poverty") and entitled it *Misère de la philosophie* (Eng. trans.,

Poverty of Philosophy, 1935). In it he developed the fundamental propositions of his economic interpretation of history. Against Proudhon's (and the utopian socialists') quest for the morally most desirable social order he put his own search for the inevitable; *i.e.*, the system that would by necessity result from the operation of historical forces. Another even more important document originated from Marx's (and Engels') pen during the stay in Brussels—*Manifest der Kommunistischen Partei* (1848, many reprints; Eng. trans. by Samuel Moore, 1888), which contains a summary of his whole social philosophy. It was written to serve as the platform of the Communist league. *The Communist Manifesto* appeared at a moment most favourable to its effectiveness: on the eve of the February (1848) revolution in France during which socialism showed its power.

The revolutionary atmosphere in Germany in 1848 made it possible for Marx to return to Cologne and revive his newspaper, now under the title of *Neue Rheinische Zeitung*, but in 1849 he was expelled. This time he settled in London, where he spent the rest of his life—most of it in dire poverty. Journalistic activity for the *New York Tribune*, whose managing editor was Charles A. Dana, a Fourierist, at times alleviated the distress, but only the generosity of Engels, who worked in the Manchester affiliate of his father's textile firm, protected the Marx family from starvation. Several of Marx's children died, among them his only son, Edgar. Of his three daughters who reached adult life, two married French socialists (Paul Lafargue and Charles Longuet); the third, after Marx's death, established an unhappy association with the British Marxist Edward Aveling and ended by suicide. Marx died on Mar. 14, 1883, 15 months after the death of his wife. He was buried at Highgate cemetery.

In spite of poverty and persistent illness, Marx proved himself a prolific writer. Anxious to apply his philosophy of history to the events in France, where civil war had broken out between the workers and the middle class in the summer of 1848, Marx wrote his booklet *Die Klassenkämpfe in Frankreich 1848 bis 1850* (1850/1859; Eng. trans. 1942) and followed it up with *Der Achtzehnte Brumaire des Louis Napoleon Bonaparte* (1852–1885; Eng. trans. by Eden and Cedar Paul, 1940)—both of them masterpieces of historiography. He gave a critical history of economic literature in his book *Zur Kritik der politischen Ökonomie* (1859, Eng. trans. by N. I. Stone, 1904). His most famous work was *Das Kapital*. (The first volume appeared in 1867; second and third volumes were published posthumously in 1885 and 1894 edited by Engels. An English translation of the first volume by Samuel Moore and Edward Aveling appeared in 1886; a translation of the second and third volumes by Ernest Untermann, 1907 and 1909.) In this book Marx developed a theory of the capitalist system and its dynamism, with emphasis on its self-destructive tendencies.

The only important organizational activity Marx ever undertook was his leadership of the International Workingmen's association, (the First International) beginning in 1864. Most of the time his own followers were only a minority among the members, but he balanced the various factions against each other with great skill and infinite patience and held out to them their common goals, until the conflict with the anarchists put an end to the International. With the British labour movement Marx had little contact, although in the International some British trade-unionists were for a time among his strongest supporters. In France, his influence during his lifetime was overshadowed by that of Proudhon (*q.v.*) and in Germany—at least up to the late 1870s—by that of Ferdinand Lassalle (*q.v.*) but Lassalle and his successor, J. B. von Schweitzer, were interpreters rather than opponents of many of Marx's ideas. (See MARXISM.)

Marx regarded tsarism as the greatest enemy of freedom in all of Europe, and he wished for a strengthening of British imperial power as a counterweight to Russia. He also had a great hatred of Napoleon III. He was opposed to Prussian hegemony over Germany as established by Bismarck but asserted the right of the German people to unity; some utterances to the contrary notwithstanding, Marx respected and even shared national feelings. Marx took a passionate interest in the American Civil War as a partisan of the North. In spite of his merciless criticism of bourgeois

BY COURTESY OF THE TRUSTEES OF THE BRITISH MUSEUM

KARL MARX

liberalism, Marx treasured the liberal-humanitarian tradition from which the socialist movement had sprung, and in all probability would have abhorred the antihumanitarian practices of present-day Communism. Marx did not live long enough to co-ordinate the strands in his great fund of ideas, and the unreconciled contradictions became a source of dissension among his intellectual heirs.

With the exception of Engels, Marx had no close, lifelong friend. To many of his contemporaries he appeared coldly arrogant, conceited and full of hate. Whether these traits were part of his nature or merely a response to his many frustrations, is a question which none of his many biographers has convincingly answered.

See also references under "Marx, Karl Heinrich" in the Index.

BIBLIOGRAPHY.—Franz Mehring, *Karl Marx* (1918; Eng. trans. by Edward Fitzgerald, 1935); Otto Rühle, *Karl Marx, His Life and Work* (1928; Eng. trans. by Eden and Cedar Paul, 1929); Gustav Mayer, *Friedrich Engels* (1934; Eng. trans. by G. and H. Highet, 1936); Moscow Institut Marxisma-Leninisma, *Karl Marx, Chronik seines Lebens* (1934); Dona Torr (trans. and ed.), *Correspondence, 1846–1895* (1934).

Writings.—An exhaustive bibliography of those of Marx's writings which have been translated into English is given in the second volume of Donald D. Egbert and Stow Persons (eds.), *Socialism and American Life* (1952). In an appendix to his biography, Mehring gives a fairly complete list of the originals. The collected edition of Marx's and Engels' writings planned by the Institut Marxisma-Leninisma has remained incomplete; the collection contains (in original German) the earliest works, the complete correspondence between Marx and Engels in four volumes (1929–31) and an annotated edition of the *Anti-Dühring* (1935), including all preparatory notes that could be found, and also Marx's comments on the draft. (C. L.)

MARX, WILHELM (1863–1946), German statesman, leader of the Centre party and twice chancellor of the *Reich* during the Weimar republic was born in Cologne on Jan. 15, 1863, the son of the headmaster of a primary school. He studied law and rose from a judgeship in the county court at Elberfeld (1894) through successive promotions to the presidency of the senate of the court of appeal at Berlin (1922). He joined the Centre party and was a deputy to the Prussian *Landtag* from 1899 to 1918 and to the *Reichstag* from 1910 to 1932. A Roman Catholic, Marx was founder and first president of the Catholic Schools organization (Düsseldorf, 1911), and worked constantly for it. After World War I he also became president of the People's Union for Catholic Germany.

Marx was chairman of the Centre party from 1921 to 1928 as well as its leader in the *Reichstag*. At the end of Nov. 1923 he took Gustav Stresemann's place as chancellor of the *Reich*, heading a minority government based on support from the middle-class parties. This government secured the acceptance of the Dawes plan in Aug. 1924 (see GERMANY: History), but Marx resigned in the following December. He was prime minister of Prussia from February to April 1925. The "Weimar coalition" put him up as candidate for the presidency of the *Reich* in 1925, but he was defeated by Paul von Hindenburg. Having been minister of justice and of the occupied territories from Jan. 1926, Marx became chancellor of the *Reich* again in May. He inclined his government toward the right in Jan. 1927 by taking the German Nationalists into it and therefore resigned in June 1928 in view of the success of the Social Democrats in the elections of May. In Dec. 1928 he also resigned from the chairmanship of the Centre party and withdrew from politics. He died in Bonn on Aug. 5, 1946. See GERMANY: History.

See histories of the Centre party; also E. Matthias and R. Morsey (eds.), *Das Ende der Parteien* (1960). (R. Mo.)

MARXISM, a body of social doctrine worked out by Karl Marx in co-operation with his friend Friedrich Engels and systematized later by some of Marx's followers, especially Karl Kautsky. Marxism is a philosophy of history, implemented by an elaborate economic theory. This philosophy purports to demonstrate the inevitability of socialism (*q.v.*) and eventually of full communism (*q.v.*), the latter to be understood as a classless, collectivist order in which the social product is distributed according to needs and in which the state, law, money and the concept of economic value have lost their functions and therefore have "withered away." The following are the most important elements of Marxist doctrine:

Determinism.—Fundamentally, Marxists believe that history is governed by laws which the human mind can recognize and which offer man a possibility to foresee the future of society in its most important characteristics. Marxist determinism has been expressed with particular vigour by Rosa Luxemburg, one of the most original minds among the Marxists, who spoke of the "granite foundation of objective historical necessity," on which Marxism has built the socialist creed, in contrast to the "fog of pre-Marxian systems and schools of thought which wanted to derive socialism merely from the injustice and wickedness of the present world and relied merely on the revolutionary determination of the workers" (from an appendix to the second German edition of her book *Die Akkumulation des Kapitals*, p. 37).

Marxist determinism promises victory to the working class and thus is apt to strengthen the latter's self-confidence in the class struggle, but at the same time the question arises as to why workers should make sacrifices in order to bring about developments which are inevitable in any event. This problem is related to, though not identical with, the issue of free will versus causal necessity as known to general philosophy. For Marxists, this fundamentally insoluble dilemma is particularly important because they regard themselves not only as scholars but also as active promoters of social change.

Economic Interpretation of History.—What are the laws that govern history and can be made the basis of social prognosis? The first of these laws is supposed to determine the direction of the historical process. In its general form, the law says that economic developments are basic to social evolution in other areas. Ideas and institutions, law and politics, even religious concepts and artistic expression are parts of the social "superstructure," inevitably changing with the gradual transformation of the economic foundation. Since technological development leads to production units of ever increasing size, bringing together ever greater masses of workers in one enterprise and requiring ever larger amounts of capital per unit of labor, only the community at large will finally be able to provide the organizational frame work of production. This conclusion is supported by the theorem that the rate of profit will inevitably decline (see below).

Marxism does not contend that ideas exercise no influence on history, but merely that they are not independent agents; as intermediary links between economic developments and outward events, ideas may be very important from a Marxist point of view. Nor do Marxists believe that man is exclusively motivated by selfish or "material" interests; they do maintain that altruism, religious devotion, patriotism or other "idealistic" feelings are themselves the products of economic conditions and of their direct and indirect effects on the human mind.

The most problematic point in the economic interpretation of history is the ambiguity of the concept of economic change. If all the developments in the field of production, distribution and consumption were included, it would seem true enough that in this wide field some causes of practically all ideological and institutional developments can be found, but also that many economic facts in this broad sense are just as much effects as they are causes of changes in the "superstructure"; for instance, changes in artistic tastes, in political institutions, in social traditions and even in religious doctrines influence consumption of commodities and thereby become determinants of production, and law is as much a determinant as it is a product of economic life. Thus a maze of mutual causal relationships results and, with cause and effect undistinguishable in many instances, no social prognosis could be built on this foundation. Marx himself nowhere gave an explicit and comprehensive presentation of his economic interpretation of history, although fragmentary expositions and allusions are dispersed over all his writings. Engels, with Marx's endorsement, supplied more extensive explanations, especially in his polemical book *Herr Eugen Dühring's Revolution in Science*, but even he did not quite clear up the meaning of the term "economic" as used in this context.

To read as much consistency as possible into the Marxist system, it must be assumed that those changes which are regarded as basic to all others are physical and for the most important part,

technological. Technological progress, although its speed is influenced by political, legal and other developments in the "super-structure," is very nearly irreversible. Under all sorts of institutional arrangements and irrespective of prevailing religious creeds and philosophies, man has improved his control over nature, although with varying degrees of effectiveness. This gradual perfection of technology depends on physical experiment and its mathematico-philosophical interpretation. Since the results can be recorded—either in memory and tradition or in books and laboratory files—the stock of knowledge about nature is certain to grow, and thus technology moves along a one-way road: toward greater human command over nature. To the extent that the social consequences of this movement can be foreseen, the Marxist claim to forecasts of social evolution has indeed a firm foundation.

The assumption that Marx meant physical change when he designated economic change as basic to all social evolution is supported by a number of examples through which Marx and Engels tried to elucidate their basic proposition. This version of the economic interpretation of history is accepted by some Marxist writers, especially Georgy Plekhanov and Nikolai Bukharin, but rejected by others, for instance by Sidney Hook.

Whatever version is accepted, one weakness remains in the economic interpretation of history. True as it is that we think in a particular way because we happen to live in an age with a particular state of technology, we also think as we do because the dominant ideas of the present age were preceded by other ideas which had exhausted their fruitfulness or were discovered to be without an adequate basis in facts. The Renaissance followed the middle ages not merely because improved shipping and perfection of all sorts of tools had increased trade, improved the crafts, opened new sea lanes and led to new discoveries, and thereby created a new type of man, but also because men by mere intellectual and spiritual effort had found the limitations of medieval thinking and feeling. The economic interpretation of history overstates its case by denying that man's intellectual and spiritual development possesses any autonomy; but this part of Marxism has greatly enriched all social sciences by drawing attention to technological progress as a cause of some very important aspects of cultural and institutional development.

The economic interpretation of history, although called "historical materialism" by Marx himself and many Marxists, has no essential relationship to philosophical materialism, and only a vague analogy exists between the two concepts.

Dialectics.—Marx tended to believe that all important historical progress is achieved through an all-out conflict between an old and a new principle of social organization, and that consequently progress would be impeded if the tension between these two principles were "prematurely" reduced by limited reforms of the old system. This belief is based on dialectic philosophy, which Marx took over directly from the German philosopher Hegel and indirectly from ancient Greek philosophers. For the consistent Marxist dialectician, straight-line, gradual progress can never lead to worthwhile results; for him, reforms represent progress only if they operate as a foreign body within the existing system and thus accelerate its death, for instance, when taxation of profits within a capitalist system is raised so high as to destroy entrepreneurs' incentive. Since true reform, which does not destroy the present system but gradually transforms it, is ruled out, revolution becomes necessary, and to a consistent believer in dialectics the suffering and sacrifices of violent change constitute the price that mankind has to pay to have any essential progress at all.

This was the philosophy that Marx professed, but he failed to show complete consistency in dealing with its implications. Apparently he was not prepared to rule out peaceful progress unconditionally, and he may also have found it difficult to reconcile dialectic philosophy with the economic interpretation of history, since technological progress is the very model of "straight-line" gradual evolution.

Class Struggle.—Marx stressed the obvious truth that social groups have conflicts of interest that are often reflected in antagonistic political creeds. He tends to go beyond this truism

by implying that the classes have no common interests at all, and that their struggle, in which he sees the great motive power of history, is essentially illimitable.

The basis of this more far-reaching belief is the connection Marxism established between the class struggle concept and dialectic philosophy. In the course of history, Marx saw each principle of social organization represented by a social class: feudalism by the nobility, capitalism by the entrepreneurs, socialism by the workers. The struggle of the classes is identical with the dialectic conflict of organizational principles. Consequently, the class struggle is governed by the law of dialectics; it is necessarily an all-out conflict—it cannot be limited by the rules of democracy, which substitute "ballots for bullets" and require respect for the inalienable rights of the opponent. The victory of the new class must be followed by repression of the former ruling class until the last vestiges of the old order are extinguished. In the struggle of the workers against the capitalists, this repression will result in the "dictatorship of the proletariat," as the political form of society in the period of transition from capitalism to full communism.

As Marx was not a consistent dialectician, he wrote many passages that are incompatible with the belief in the illimitable class struggle. There exists, therefore, a cleavage in the Marxist system between the belief in democratic evolution and the contrary belief in the inevitability of revolution ending in dictatorship. This cleavage has transmitted itself to Marx's disciples and is reflected by the conflict between the supporters of democratic socialism, many of whom still treasure the Marxist tradition, and those of modern Communism. Intermediate positions between these two extremes were once held by writers like Kautsky, but this old Marxist "centre" has in the main joined the democratic camp. Some developments within the Communist camp, especially but not exclusively in Poland and Yugoslavia, indicate a possibility that a new Marxist centre may arise.

Labour Value Theory.—Marx accepted the explanation of value as given by the classical economists of his day, especially David Ricardo (*q.v.*). According to the classical doctrine, the value of a commodity depends on the amount of labour time necessary for its production. Marx applied this theory with some refinements to human labour power. According to him a worker's labour power is sold like any other commodity, at a price determined by the labour time necessary to produce it (the time necessary to produce the means of subsistence and education). Labour power, however, is the only commodity that can produce a value greater than its own, because a worker can work more hours than are necessary to keep him alive and in a position to reproduce his kind. The product of this "surplus labour" is called "surplus value" and is appropriated by the employer who has acquired the legal right to the full use of labour power by paying the worker the labour-time value of that power. This surplus value is the source of all nonwage income: profit, rent and interest. The purchase of labour power at a price corresponding to its labour-time value and therefore inevitably smaller than the labour-time value of the products is called "exploitation of labour" by Marx—a term which, according to Marx's own allegation, was not intended as an ethical condemnation but which he nevertheless often used in a sense implying a moral judgment.

In elaborating the theory that "exploitation of labour" is the only source of profit, (in the third volume of *Das Kapital*), Marx ran into difficulties that caused him to deviate from the logical consequences of the labour value theory on which he had based his initial propositions. This widely discussed self-contradiction, however, merely adds one more argument to the body of proofs by which modern theory has refuted the explanation of value from labour time. Yet the labour theory of value, and its derivative, the surplus value theory, cannot be eliminated from the Marxist system as some recent Marxists and semi-Marxists have suggested, for these theories are indispensable for the support of the proposition that capitalism is doomed by objective economic necessity—a proposition that belongs to the very essence of Marxism.

Since all profit results from "exploitation of labour," the rate of profit—the amount per unit of total capital outlay—depends

largely on the number of workers employed. Machines cannot be "exploited"; they can therefore not contribute to total profits, although they help labour produce more useful things. Only payroll capital—"variable capital"—is productive of surplus value and consequently of profit. The introduction of machines is profitable for the individual entrepreneur, to whom they give an advantage over his competitors, but as outlay for machinery grows in relation to outlay for wages, profit declines in relation to total capital outlay. The capitalist will receive less and less per hundred dollars of capital and can only try to postpone his bankruptcy by pressure upon the workers; finally, the "capitalist class becomes unfit to rule, because it is incompetent to assure an existence to its slave within his slavery." Consequently the system collapses and the working class inherits the power.

Theory of Alienation.—One of the many subsidiary doctrines contained in Marx's writings has recently attracted much interest: the contention that, for the worker under industrial capitalism, work is merely a means to protect himself from starvation, whereas for the medieval craftsman, or even the peasant, work was also a means of self-expression. To the extent that this "alienation" of man from his work really exists, it is obviously a result of the fragmentation of the work process through division of labour. Marx does not wish to return to medieval methods of production, but he believes that modern technology when freed from the fetters of capitalist profit calculation will liberate modern man from the tie to one particular occupation, will permit him to change his activities frequently enough to make him visualize every phase of his work as part of the social process of production and thus find new satisfaction. There is nothing in technological development, however, or in collectivist experience since Marx's days to support these particular expectations; on the other hand, the replacement of manual labour by machines in some of the most tedious jobs and the shortening of the working day have certainly alleviated the alienation problem.

Appraisal of Marxism.—In spite of its weaknesses, Marxism has played a role greater than any other recent system of social philosophy; its effects cannot be summarized by a simple formula. Marxism has strengthened the workers' movement which has been the greatest single force operating for social justice; it has reconciled the workers to modern technology, imbued them with a great respect for intellectual accomplishment and strengthened their desire for education; more effectively than any other school, it has called attention to the role of economic and especially of technological factors in history. On the other hand, it has supplied totalitarian enemies of freedom with important intellectual weapons. Marxism is the only admissible social doctrine in the Soviet Union and the "People's Democracies," although more recently the inadequacies of the labour value theory as a basis for rational planning have caused important, if tacit, modifications of Marxism.

Austro-Marxism.—In its orthodox form, Marxism denies the existence of any "super-class ethics": all moral rules are considered reflections of the social position of either the dominant class or of the oppressed class. In opposition to this view, an effort was made, mainly by Austrian socialists, to return to the pre-Marxian idea that the socialist postulates should be based on an ethical code binding on all humanity while most other elements of Marxist thought were retained. This open acknowledgment of the ethical basis of socialism was incompatible with the more extreme versions of the class struggle concept, since ethical rules which determine the ultimate ends of a movement also have a bearing on the legitimacy of means. Austro-Marxism might therefore have supplied the right-wing of the socialist movement with a badly needed theoretical basis, but most of the Austro-Marxists, as, for instance, their most prominent leader, Otto Bauer, kept politically close to the Marxist centre group.

Neo-Marxism.—In his analysis of capitalism, Marx had been concerned almost exclusively with a highly competitive kind of capitalist system in which the entrepreneurs were in the main opposed to state intervention. The decades after Marx's death produced a kind of capitalism that was permeated with monopoly and in which the majority of businessmen desired state intervention for the protection of monopolies, for protective tariffs and

for the opening of foreign markets and promotion of foreign investments. A number of Marxists writers tried to modify Marxist theory in order to account for these new facts and to exploit them for the strengthening of Marxist policy arguments.

The first of these Neo-Marxists was Rudolf Hilferding (1895) who in his book *Das Finanzkapital* (1910) maintained that the increasing influence of the banks over industry was mainly responsible for cartelization—because the banks wanted to prevent their industrial customers from ruining each other through competition—and also for the search for foreign capital outlets. For the latter phenomenon, Rosa Luxemburg (q.v.) offered a new explanation in her book *Die Akkumulation des Kapitals* (1913). From Marx's discussion of the interdependence of consumer and producer goods industries she drew the conclusion that capitalism was threatened with a glut of consumer goods and maintained that this threat was the motive power behind the imperialist ventures of capitalist states—ventures which she regarded as temporarily successful but necessarily futile in the end. Fritz Sternberg in his book *Der Imperialismus* (1926), tried to clear up the many obscurities in Luxemburg's reasoning and supplemented it with an argument which, from a Marxist point of view, seemed more convincing: since the colonial areas use more manual labour and less machinery, the decline of the rate of profit has not advanced as far there as in the old industrial countries; therefore, investment in colonies and semicolonies offers the western capitalists a temporarily higher profit rate. This latter argument was further expounded by the Polish writer Henryk Grossmann in his book *Das Akkumulations- und Zusammenbruchsgesetz des kapitalistischen Systems* (1929). Finally, E. J. Strachey gave a comprehensive presentation of the Neo-Marxist theory of imperialism and capitalist doom in *The Nature of Capitalist Crisis* (1935), using mainly the argument of the higher profit rate in noncapitalistic areas.

The historic significance of Neo-Marxism rests upon its utilization by Lenin in his book *Imperialism, the Highest State of Capitalism* (1916). Lenin did not commit himself to the details of Rosa Luxemburg's analysis but took from it the general idea that western capitalism had prolonged its life by expanding into colonial areas; he drew the conclusion that capitalism would perish if deprived of its colonial domains. Under the spell of this thought Bolshevism staged its anti-imperialist campaign in which it achieved major successes but also encountered conflicts with the rising nationalism of the ex-colonials—conflicts which seem to increase as "capitalist" imperialism becomes a thing of the past.

MARY (THE VIRGIN MARY), the mother of Jesus. Out of the sparse details of her life as portrayed in the Gospels, Christian piety and theology have constructed a picture that fulfils the prediction ascribed to her in the Magnificat (Luke i, 48): "Henceforth all generations will call me blessed."

It would be impossible to write a biography of Mary based upon biblical accounts, in spite of the fact that the span of time covered by those accounts is longer than the life of Jesus. The first mention of her is the story of the annunciation, which reports that she was living in Nazareth (Luke i, 26 ff.); the last mention of her (Acts i, 14) includes her in the company of those who devoted themselves to prayer after the ascension. Between these two references are several scenes of a rather occasional character: the visit with Elizabeth, her cousin and the mother of John the Baptist (Luke i, 39 ff.); the birth of Jesus and the pre-

entation (Luke ii, 1 ff.); the coming of the Magi and the flight to Egypt (Matt. ii, 1 ff.); the Passover visit to Jerusalem (Luke ii, 41 ff.); the marriage at Cana in Galilee (John ii, 1 ff.); the attempt to see Jesus while he was teaching (Mark iii, 31 ff.); the station at the cross, where, apparently widowed, she was entrusted to John (John xix, 26 ff.). Even those interpreters for whom these scenes have represented a series of literal historical accounts have found it difficult to draw a portrait of Mary on the basis of them.

But since the early days of Christianity, the themes which these scenes symbolize have been the basis for thought and contemplation about Mary, developing and expanding through the centuries. Christian communions and theologians differ from one another in their interpretation of Mary principally on the basis of where they set the terminal point for such development and expansion. To a considerable degree, therefore, a historical survey of that development is also an introduction to the state of contemporary Christian thought about Mary.

Guarantee of the Incarnation.—Probably the earliest allusion to Mary in Christian literature is the phrase "born of a woman" in Gal. iv, 4. As parallels like Job xiv, 1 and Matt. xi, 11 suggest, the phrase is a Hebraic way of speaking about the essential humanity of a person. When applied to Jesus, therefore, it was intended to assert that he was truly a man, in opposition to the attempt, later seen in the Docetists, to deny that he had a completely human life (see *Docetism*). It seems unwarranted to read anything further into the phrase, as though "born of a woman" necessarily implied "but not of a man and a woman." Thus the phrase made of Mary the guarantee of the reality of the incarnation. For the ancient world, one human parent was necessary to assure that a person was genuinely human, and one of the roles assigned to Mary from the beginning has been that of providing this assurance. Some historians have even maintained that the primary connotation of the phrase "born of the Virgin Mary" in the Apostles' Creed was this same insistence by the church upon the reality of the incarnation. That insistence has been the irreducible minimum in all the theories about Mary that have appeared in Christian history. Those who deny the virgin birth usually claim to do so in the name of this insistence upon true humanity. Those who defend the virgin birth usually maintain that the true humanity was made possible when the Virgin accepted her role as the guarantee of the incarnation (Luke i, 38): "Let it be done to me according to thy word." This is the original source of the title "coredemptrix" assigned to Mary in Roman Catholic theology, though the term has come to connote a more active participation by the Virgin in the redemption of mankind; the precise nature of this participation is still a matter of controversy among Catholic theologians.

Virgin Mother.—By far the most voluminous narratives about Mary in the New Testament are the infancy stories in Matthew and Luke. In their present form, both accounts make a point of asserting that Jesus was conceived in the womb of Mary without any human father (Matt. i, 18 ff.; Luke i, 34 ff.); the many textual variants in Matt. i, 16, some of them with the words "Joseph begat Jesus," have caused some scholars to question whether such an assertion was part of Matthew's original account. The most voluminous discussions of Mary in postbiblical Christian literature have also been those dealing with her virginity. The narratives in Matthew and Luke seem to be the only references to the matter in the New Testament, unless John i, 13 is taken to read "... who was born" rather than "... who were born." On the basis of these narratives, it was the unanimous teaching of all the orthodox fathers of the church that Mary conceived her Son with her virginity unimpaired, a teaching enshrined in the Apostles' Creed and concurred in by the classical Reformers as well as by most Protestant believers since the Reformation. Only with the rise of Protestant theological liberalism did this teaching begin to lose the universal support it had enjoyed. One of the major points in the attack by fundamentalism upon this liberalism was its insistence upon the literal accuracy of all the miracle stories in the Bible, including and especially those dealing with the miraculous conception of Jesus.

Mother of God.—The first major theological controversy over Mary had to do with the propriety of applying to her the title of *Theotokos*, "God-bearer" or "mother of God." The title itself was a logical deduction from the dogma of the full deity of Christ as this was established during the 4th century, and those who defended that dogma were also the ones to draw the deduction. By the end of the 4th century, therefore, it had successfully established itself in various sections of the church. Because it seemed to him that the supporters of the title were confounding the divine and the human in Christ, Nestorius objected to its use, preferring the less explicit title *Christotokos*. Along with other aspects of his teaching, Nestorius' objections were condemned at Ephesus in 431, and *Theotokos* was unconditionally approved (see *COUNCIL: Councils to the 9th Century*). In the devotion of Eastern Christendom the *Theotokos* (Russian *Bogoroditsa*) has played a major role, also becoming one of the favourite subjects for icon painters. Through its incorporation in the Ave Maria, the title "mother of God" has been circulated throughout western Catholicism. By the approval it received in both Lutheran and Reformed confessions during the period of the Reformation, the title assured itself a place in the theology, if not in the piety, of orthodox Protestantism. It is as mother of God that the Virgin is also termed mediatrix. The official teaching of the Roman communion has sought to make clear that this latter term is not intended to detract from the glory of Christ as sole Mediator, but that Mary mediates between Christ and mankind as she did at Cana in Galilee (John ii, 3).

Ever Virgin.—One corollary that could be deduced from the New Testament assertion of Mary's virginity in the conception of Jesus was the doctrine of her perpetual virginity, not only "before birth" but "in birth and after birth," to use the usual phrases. The Apostles' Creed appears to teach at least her virginity "in birth" when it says "born of the Virgin Mary." Although the earliest mention of the doctrine occurs in the apocryphal Protevangelium Jacobi, its origins and extent are not easy to trace, Roman Catholic historians and Protestant historians coming to contradictory conclusions. The doctrine had no explicit warrant in the New Testament, and Old Testament passages such as Ezek. xlv, 2 and Song of Sol. iv, 12 were probably convincing only to those who already believed the doctrine. In addition, the doctrine posed two problems of biblical interpretation, both of which were discussed in detail by defenders of the doctrine from Jerome to Luther. To the argument from words such as "until" (Matt. i, 25), "before" (Matt. i, 18) and "first-born" (Luke ii, 7) that Mary must have borne further children, the defenders of the perpetual virginity have replied that none of these words speaks at all about what followed: an only child is a first-born child, and a man who "died before repenting of his sins" did not necessarily repent thereafter. The other biblical problem was that of the "brothers" of Jesus referred to in I Cor. ix, 5, Gal. i, 19, and several times in the Gospels and in Acts. Defenders of the perpetual virginity have explained these either as "kinsmen" or as children of Joseph by a previous marriage or as children of another Mary and of Cleophas. Partly because of these problems, the doctrine of the perpetual virginity of Mary has not been supported as unanimously as has the doctrine of the virginal conception or the title "mother of God." It achieved dogmatic status at the Council of Chalcedon in 451, and is therefore binding upon Eastern Orthodox and Roman Catholic believers; in addition, it is maintained by many Anglican, some Lutheran and a few other Protestant theologians.

Immaculate.—As the doctrine of her perpetual virginity implied an integral purity of body and soul, so, in the opinion of many early theologians, she was also free of other sins. In a discussion aimed at proving the universality of sin, Augustine spoke for the western church when he wrote: "We must except the holy Virgin Mary. Out of respect for the Lord, I do not intend to raise a single question on the subject of sin. After all, how do we know what abundance of grace was granted to her who had the merit to conceive and bring forth Him who was unquestionably without sin?" (*Nature and Grace*, ch. 36). But it was the distinction between original sin and actual sin, firmly established in western theology by the same Augustine, that eventually compelled a

further clarification of what the sinlessness of Mary meant. Certain eastern theologians in the 4th and 5th centuries were willing to attribute actual sins to her, but most theologians in both east and west came to accept the view that she never did anything sinful, a view that found expression even among the Reformers. But was she free from original sin as well? And if so, how? Thomas Aquinas took a representative position when he taught that her conception was tarnished, as was that of all men, but that God suppressed and ultimately extinguished original sin in her, apparently before she was born. But this position was opposed by the doctrine of the immaculate conception (*q.v.*), systematized by Duns Scotus and finally defined as Roman Catholic dogma in 1854. According to this dogma, Mary was not only pure in her life and in her birth, but "at the first instant of her conception was preserved immaculate from all stain of original sin, by the singular grace and privilege granted her by Almighty God, through the merits of Christ Jesus, Savior of mankind."

Assumed Into Heaven.—When the immaculate conception was promulgated, petitions began coming to the Vatican for a definition regarding the assumption of the Virgin into heaven, as this was believed by most Roman Catholics and celebrated in the feast of the assumption (*q.v.*). During the century that followed, more than 8,000,000 persons signed such petitions; yet Rome hesitated, the doctrine being difficult to define on the basis of Scripture and early witnesses to Christian faith. No account of the place and circumstances of Mary's death was generally accepted in the early church, no burial place acknowledged, and no miracles credited to relics of her body. But such arguments from silence did not suffice to establish a dogma, and on the positive side even the earliest doctrinal and liturgical tradition appeared relatively late in history. Pope Pius XII made the dogma official in 1950, declaring "that the immaculate mother of God, the ever Virgin Mary, when the course of her earthly life was run, was assumed in body and in soul to heavenly glory." As it was formulated, the dogma left open to speculation the question of Mary's death.

In addition to these official titles and roles assigned to her by Catholic Christianity, the Virgin has served to symbolize the redemption of the life of nature and to provide a bridge between Christianity and those religions of nature that have spoken of this redemption. In the secular life and literature of the west since the day of the *Minnesänger*, she has symbolized the nobility of woman. Even those non-Roman churches which have most vigorously criticized the "Mariolatry" they claimed to find in the dogmas of the immaculate conception and the assumption have frequently addressed praises to her in their hymnody that they would have hesitated to express in the prose of their dogmatic theology. Thus, in ways she could never have anticipated, all generations have called her blessed.

BIBLIOGRAPHY.—Juniper Carol, O.F.M. (ed.), *Mariology*, 3 vol. (1955 *et seq.*), deals successively with the sources of Marian doctrine, with Marian theology and with Marian devotions. For individual Marian prerogatives, studied from the viewpoint of Scripture and of positive and speculative theology, see the annual *Marian Studies* (proceedings of the Mariological Society of America) (1950 *et seq.*). The Eastern Orthodox view is presented, though from a Roman standpoint, by Maurice Gordillo, *Mariologia Orientalis* (1954). Anglican, Lutheran, Protestant and Orthodox reactions to the assumption, as well as a detailed Marian bibliography, are in Friedrich Heiler (ed.), *Das neue Mariendogma* (1951).

(J. J. PN.)

MARY I (1516–1558), queen of England from 1553 to 1558, was the daughter of Henry VIII and Catherine of Aragon. Mary was born at Greenwich, on Feb. 18, 1516, and she was baptized two days later, Thomas Cardinal Wolsey standing as her godfather. She seems to have been a precocious child and is reported, when scarcely four and a half years old, as entertaining some visitors by a performance on the virginals. When she was little over nine, she was addressed in a complimentary Latin oration by commissioners sent over from Flanders on commercial matters and replied to them in the same language "with as much assurance and facility as if she had been twelve years old." About that time her father, who was proud of her achievements, was arranging that she should learn Spanish, Italian and French. A great part, however, of the credit for her early education was undoubtedly due to her mother,

who not only consulted the Spanish scholar Juan Luis Vives upon the subject but was herself Mary's first teacher in Latin.

When Mary was two years old, she was proposed in marriage to the dauphin, son of Francis I. Three years later the French alliance was broken off and she was affianced to her cousin, the young emperor Charles V, by the treaty of Windsor in 1522. However, after his great victory over Francis at Pavia in 1525, Charles released himself from this engagement and made a more convenient match. Later in the same year Mary was given an establishment of her own and was sent to Ludlow with a council which was designed to secure the better government of the marches of Wales. For several years she accordingly kept her court at Ludlow, while new arrangements were made for the disposal of her hand. She was now proposed as a wife, not for the dauphin as before, but for his father Francis I, who had just been redeemed from captivity at Madrid, and who was only too glad of an alliance with England to mitigate the severe conditions imposed on him by the emperor. When the Anglo-French alliance was finally concluded, however, by a treaty dated Westminster, April 30, 1527, it was provided that Princess Mary should be married either to Francis himself or to his second son, Henry, duc d'Orléans.

The Succession Problem.—It was immediately after this treaty that Henry VIII began the proceedings for his "divorce" from Catherine that were to make the next nine years perhaps the most miserable period of Mary's life. From the end of 1531 mother and daughter were kept apart. Possibly Queen Catherine had the harder trial, but Mary's was scarcely less severe. On the birth of Anne Boleyn's daughter Elizabeth (Sept. 1533), Mary was required to give up the dignity of princess and acknowledge the illegitimacy of her own birth. On her refusal her household was broken up, and she was sent to Hatfield to act as lady-in-waiting to her own infant half sister. Nor was even this the worst of her trials; she feared that her very life was in danger from the hatred of Anne Boleyn. Mary's health, moreover, was indifferent, and even when she was seriously ill, although Henry sent his own physician, Dr. Buttes, to attend her, he declined to let her mother visit her. At her mother's death in Jan. 1536 she was forbidden to take a last farewell of her.

But in May following another change occurred. Anne Boleyn her bitterest enemy, fell under the king's displeasure and was put to death. Mary was then urged to make a humble submission to her father as the means of recovering his favour, and after a good deal of correspondence with the king's secretary, Thomas Cromwell, she eventually did so. The terms exacted of her were bitter in the extreme, but Mary, alone and at the mercy of her imperious father, at length subscribed an act of submission, acknowledging the king as "Supreme Head of the Church of England under Christ," repudiating the pope's authority, and confessing that the marriage between her father and mother "was by God's law and man's law incestuous and unlawful."

Henry was reconciled to her and gave her a household in some degree suitable to her rank. During the rest of the reign her position was less difficult. She appeared at the court and a number of new marriage projects for her were made, though all of them came to nothing. Although she was still treated as of illegitimate birth, in 1544 she was restored by statute to a position in the succession next after Edward and any other legitimate children who might be born to the king, but under conditions to be regulated by Henry's will.

Under Edward VI.—During the reign of her brother, Edward VI, Mary was again subjected to severe trials, which at one time made her seriously meditate escaping abroad. Edward himself seems to have been personally kind to her, but the religious inno-

BY COURTESY OF THE MUSEO DEL PRADO
MARY I, DETAIL OF A PORTRAIT BY
SIR ANTHONY MORE, 1553

ventions of his reign soon brought her into conflict with the government. She had done sufficient violence to her own convictions in submitting to a despotic father and was not disposed to yield an equally tame obedience to authority exercised by a factious council in the name of a younger brother not yet come to years of discretion. Besides, the cause of the pope was naturally her own. In spite of the declaration formerly wrung from herself, most people did not regard her as a bastard although the full recognition of her rights implied the recognition of the pope as head of the church. Hence, when Edward's parliament passed the Act of Uniformity in 1549, enjoining services in English and communion in both kinds, she insisted on having mass in her own private chapel under the old form. When ordered to desist, she appealed for protection to her cousin, the emperor Charles V, who intervened for some time not ineffectually, threatening war with England if her religious liberty was infringed.

But Edward's court was composed of factions of which the most violent eventually carried the day. Lord Seymour, the admiral, was attainted of treason and beheaded in 1549. His brother, the protector Somerset, met with the same fate in 1552. John Dudley, duke of Northumberland, by then paramount in the privy council, easily obtained the sanction of the young king to those schemes for altering the succession which led immediately after Edward's death (July 6, 1553) to the usurpation of Lady Jane Grey. Northumberland had, in fact, overawed the rest of the privy council, and when Edward died, he took such energetic measures to give effect to his scheme that Lady Jane was actually recognized as queen for some days, and Mary had to flee from Hunsdon into Suffolk. But the country was devoted to her cause, as indeed her right in law was unquestionable, and before many days she was royally received in London and took up her abode within the Tower of London.

Queen 1553-58.—Her first acts as queen displayed a character very different from that which she still holds in popular estimation. Her clemency toward those who had taken up arms against her was remarkable. She released from prison Lady Jane's father, the duke of Suffolk, and had difficulty even in signing the warrant for the execution of Northumberland. Lady Jane herself she fully meant to spare, and did spare till after Sir Thomas Wyatt's formidable insurrection in 1554. Her conduct, indeed, was in most respects conciliatory and pacific, and so far as they depended on her personal character the prospects of the new reign might have appeared altogether favourable.

But her position was one of peculiar difficulty, and the policy on which she determined was far from judicious. Inexperienced in the art of governing, she had no trusty councillor but Stephen Gardiner, bishop of Winchester; and she was naturally led to rely even more on the advice of her cousin, the emperor, who had been her mother's friend in adversity and had helped Mary in the preceding reign. Following the emperor's guidance, she determined almost from the first to make his son Philip her husband, though she was 11 years his senior. She was also strongly desirous of restoring the old religion and wiping out the stigma of illegitimacy upon her birth.

Of all these objects her marriage was the most unpopular. Restoration of the old religion might deprive the new owners of abbey lands of their comfortable acquisitions; and it was only with an express reservation of their interests that the thing was actually accomplished. A declaration of her own legitimacy necessarily cast a slur on that of her sister Elizabeth and cut her off from the succession. But the marriage promised to throw England into the arms of Spain and place the resources of the kingdom at the command of the emperor's son.

The commons sent her a deputation to entreat that she would marry an Englishman, and when her resolution became known early in 1554, insurrections broke out in different parts of the country. Suffolk, whose first rebellion had been pardoned, proclaimed Lady Jane Grey again in Leicestershire, while Wyatt raised the county of Kent and, though denied access by London bridge, led his men around by Kingston-upon-Thames to the very gates of London before he was repulsed. In the midst of the danger Mary showed great intrepidity and the rebellion was pres-

ently quelled. Thereupon she married Philip (July 25, 1554), restored Catholicism and admitted Reginald Cardinal Pole to absolve the kingdom from its past disobedience to the Holy See (Nov. 30, 1554).

It was a more than questionable policy thus to ally England with Spain—a power then actually at war with France. By the treaty, indeed, England was to remain neutral; but in the end it was drawn into the quarrel. Meanwhile the country was full of faction, and seditious pamphlets of Protestant origin inflamed the people with hatred against the Spaniards. Philip's Spanish followers met with ill-usage everywhere, and violent outbreaks occurred. A year after his marriage Philip went over to Brussels to receive from his father the government of the Low Countries and afterward the kingdom of Spain. To Mary's distress, his absence was prolonged for a year and a half and when he returned in March 1557 it was for the purpose of getting England to declare war on France. As soon as this purpose was achieved he went back to Brussels in July, to return no more to England.

In spite of the encouragement that France had given to disaffection among Mary's subjects, there had been strong opposition to Philip's demands among Mary's advisers. But an attempt by Thomas Stafford and other English refugees in France to seize Scarborough played into her hands, and she was able to declare war against the French on June 7, 1557. In this war Mary found herself opposed by the pope, who took part with France against Spain; Scotland, too, soon declared war upon her; and on Jan. 5, 1558, she suffered the final calamity of the loss of Calais.

Religious Policy.—The persecution of the Protestants, which has cast so much infamy upon her reign, did not begin until Mary had been more than a year and a half on the throne. When the kingdom was reconciled to Rome and absolved by Cardinal Pole, it was natural and logical that the old heresy laws should be revived by act of parliament. But Mary must bear the final responsibility for the severity of their enforcement, which was unprecedented in England. Merciful and kindly by nature, she yet seems to have felt that the Protestants' stern fanaticism and ill will to the old religion made them dangerous, even to the public peace; and that the persecution was necessary if the old faith were to be preserved in England. John Rogers, the first of the martyrs, was burned on Feb. 4, 1555. John Hooper, bishop of Gloucester, had been condemned six days before and suffered the same fate on Feb. 9. From this time the persecution went on uninterrupted for almost four years, numbering among its victims Nicholas Ridley, Hugh Latimer and Thomas Cranmer. It came to an end at last on the death of Mary. Nearly 300 victims are known to have perished at the stake, and their fate created a revulsion against Rome that nothing else was likely to have effected and earned Mary the nickname of "Bloody Mary." Mary was of weak constitution and subject to frequent illnesses, both before and after her accession. One special infirmity caused her to believe a few months after her marriage that she was with child, and thanksgiving services were ordered throughout the diocese of London in Nov. 1554. The same delusion recurred in April 1558 when, though she did not make her expectation public, she drew up a will in anticipation of the dangers of childbirth, constituting her husband regent during the minority of her prospective heir. To this she added a codicil on Oct. 28 following, when the illness that was to be her last had set in, showing that she had ceased to have much expectation of maternity, and earnestly entreating her "next heir and successor by the laws" (whom she did not name) to allow execution of the instrument. She died on Nov. 17, 1558.

Her name perhaps deserved better treatment than it has generally met with; her kindness to the poor is undoubted, and the severe execution of her laws seemed to her a necessity. Moreover, she was alive to the injustice with which the law was usually strained in behalf of the prerogative; and in appointing Sir Richard Morgan chief justice of the common pleas she charged him "not to sit in judgment otherwise for her highness than for her subjects," and to avoid the old error of refusing to admit witnesses against the crown. Mary's conduct as queen was governed by the best possible intentions; and it is evident that her religious zeal caused most of the trouble she brought upon herself. Her sub-

jects were entirely released, even by papal authority, from any obligation to restore the confiscated lands of the church. But she herself made it an object, at her own expense, to restore several of the monasteries; and courtiers who did not like to follow her example encouraged the fanatics to spread an alarm that it would even yet be made compulsory. So the worldly minded joined hands with godly heretics in stirring up enmity against her. Her unpopular foreign marriage and the national humiliations which followed upon it made their task all too easy.

MARY II (1662–1694), queen of England and wife of King William III, elder daughter of James, duke of York (afterward King James II), by his first wife, Anne, daughter of Edward Hyde, 1st earl of Clarendon, was born in London on April 30, 1662. She was brought up as a Protestant and in Oct. 1677 was betrothed to her cousin, William, prince of Orange; they were married in London on Nov. 4. Despite her status as heir presumptive to the crown after her father, Mary had little influence in English politics between 1677 and 1687; she did not visit England and devoted herself instead to her duties as a princess of Holland. She became much beloved by the Dutch people, and she returned their affection and devotion. Her childlessness and her husband's relations with Elizabeth Villiers naturally caused her pain, but she and William remained a devoted and united couple; her religious and political beliefs led her to defer to him at all times.

In 1687–88 the open quarrel between her husband and her father over James's religious policy brought her more into the public eye, but she continued to leave the initiative to William and his advisers. In the autumn of 1688 she agreed to support his invasion of England, because she conceived it to be her duty as a Protestant and because she suspected that her half brother James Edward, born in June 1688, was a supposititious child. After James II's flight she went to England, in Feb. 1689, and at once rejected the proposals of those who wished to make her sole monarch or sole regent, to the exclusion of her husband. Thus she and William were proclaimed joint sovereigns and crowned on April 11, 1689.

During her husband's yearly absences in Ireland and Flanders, Mary administered the government in her own name but always on his advice; and though she enjoyed great popularity as an Anglican and an Englishwoman, in contrast to the Dutch Presbyterian king, she never encouraged the formation of any party round her, and when William was in England she was glad to retire from politics altogether. She was unhappy at leaving Holland and never settled down in England, and she was deeply troubled by her anomalous position with regard to her father. A bitter quarrel with her sister Anne, and the hostility to the regime of her maternal uncles, the earls of Clarendon and Rochester, weighed further on her mind, and she aged rapidly. She died of smallpox at Kensington palace on Dec. 28, 1694, at the age of 32, and was buried in Westminster abbey.

Her husband's bitter grief was matched by the nation's, and her people sincerely mourned a selfless, deeply Christian woman whose kindness, sweetness of temper and good nature never degenerated into weakness. Her relations with the Anglican Church and with many of its leaders, such as Thomas Tenison and Gilbert Burnet, were particularly close, and her death robbed it of a valuable patron. Among her many charitable works was Greenwich Hospital for Seamen, completed after her death as a memorial. Her

Dutch tastes had a marked influence on English pottery, garden layout and interior decoration, and she was closely associated with the rebuilding of Hampton Court and Kensington palaces by Wren and the redesigning of their gardens.

MARY (MARY TUDOR) (1496–1533), queen consort of Louis XII of France, was the younger surviving daughter of Henry VII of England and Elizabeth of York and was born, probably in March, in 1496. The treaty of Calais (Dec. 21, 1507) arranged for her marriage with the future emperor Charles V when the prince reached the age of 14, and the wedding was celebrated by proxy in 1508. The contract was renewed (1513) by Henry VIII, but the emperor Maximilian I was then in treaty for a marriage with Renée of France for his son and evinced an intention to withdraw from the contract. He was forestalled by Thomas (later Cardinal) Wolsey, who arranged, by the peace of 1514, the marriage of Mary with Louis XII of France. The marriage was celebrated at Abbeville on Oct. 9. The bridegroom was a broken man of 52; the bride a beautiful, well-educated and charming girl of 18, who was already in love with Charles Brandon, duke of Suffolk. Mary was crowned queen of France on Nov. 5, 1514; on Jan. 1, 1515, King Louis died. Mary had only been induced to consent to the marriage with Louis by the promise that, on his death, she should be allowed to marry the man of her choice. But the dukes of Lorraine and Savoy were mentioned as possible suitors, and meanwhile the new king, Francis I, was making advances to her.

Suffolk himself was at the head of the embassy which came from England to congratulate the new king, and he used the opportunity to win the hand of the queen. Mary feared opposition, and, in spite of Suffolk's promise to the king to delay any action until after his return, she persuaded him to marry her secretly before he left Paris. Suffolk was ultimately pardoned through Wolsey's intercession, on payment of a heavy fine and the surrender of all the queen's jewels and plate. The marriage was openly solemnized at Greenwich on May 13, 1515. Mary died on June 24, 1533. By the duke of Suffolk she had three children: Henry, born on March 11, 1516, created earl of Lincoln (1525), who died young; Frances, born on July 16, 1517, the wife of Henry Grey, 3rd marquess of Dorset, and mother of Lady Jane Grey (q.v.); and Eleanor.

MARY (MARY STUART) (1542–1537), only surviving child of James V of Scotland and his second wife, Mary of Lorraine, was born at Linlithgow palace on Dec. 7 or 8, 1542. Her father died on Dec. 14 and Mary therefore inherited the crown of Scotland when she was only a week old. Five and a half years later her mother sent her to be brought up in France; she set sail in Aug. 1548, accompanied by four little girls, the "Maries"—Mary Beaton, Mary Fleming, Mary Livingstone and Mary Seton. For the next

ten years she lived at the gay and elegant French court, where she was betrothed to the dauphin and was the protégée of her mother's brothers, the all-powerful family of Guise. Her intelligence was great, her charm and natural grace extraordinary, and her education made her subtle and sophisticated.

On April 24, 1558, she was married to the sickly young dauphin, (who became King Francis II in July 1559), but queen consort of France and queen regnant of Scotland were not the only destinies Mary had in view. Catholics denied the validity of Henry VIII's marriage to Anne Boleyn; Elizabeth Tudor in their view

was illegitimate, and the rightful queen of England, on the death of the childless Mary Tudor (Mary I), would, therefore, be Mary Stuart, the granddaughter of Henry VII's daughter Margaret, who had married James IV of Scotland. When Mary Tudor died (Nov. 1558), Mary Stuart and her husband assumed the royal arms of England, and eight months after the accession of Elizabeth I, the English ambassador at Paris heard the heralds cry at Mary Stuart's approach: "Make way for the queen of England." Mary was queen of France for less than 18 months. On her young husband's death in Dec. 1560, she saw no future for herself with her inimical mother-in-law Catherine de Médicis acting as regent for the child Charles IX, and her Guise uncles in eclipse. She therefore accepted the invitation of her nobility to return to Scotland.

Personal Rule in Scotland.—Her mother, the queen regent, had died in June 1560, after being defeated in the struggle between the Catholic, pro-French faction and the Protestant-nationalist faction. The latter had been aided by Elizabeth I, who feared that the French stronghold in Scotland would be used as a base for the French invasion of England. The civil war had been concluded by the treaty of Edinburgh (July 1560), one of the clauses of which acknowledged Elizabeth as rightful queen of England. Mary made excuses not to sign this treaty; Elizabeth, therefore, refused her a passage through England, and Mary performed the journey by sea, arriving at Leith on Aug. 19, 1561, in a dark sea fog. The contrast of the scene she had left with that to which she had come was almost overwhelming, but her courage rose at the challenge, and her youth, beauty and graciousness made at first a most favourable impression.

Of the dominant Protestant faction, the three outstanding figures were Mary's bastard half brother, Lord James Stuart whom she created earl of Moray; William Maitland of Lethington, the ablest man in Scotland; and the Calvinist preacher John Knox, whose ferocious rudeness to his queen, on account of her religion, Mary met with a remarkable blend of simplicity and dignity. Though a devout Catholic, Mary was not by temperament a religious persecutor and when she afterward (Oct. 1564) promised the pope to root out heresy in Scotland, it was to secure his help in her designs on England. At first she did not try to injure Protestantism, only demanding freedom to practise Catholicism.

Mary was faced by unavoidable difficulties; power had shifted from the crown to the nobles, the heads of powerful clans, and the majority of the nation now abhorred Catholicism, but her first years of rule, in which she was guided by Moray, were marked by sense, good will and courage. But her obsession with the idea of becoming queen of England detracted from her chances of success as queen of Scotland. She spoke of that kingdom as her "small portion," with which she must needs be content till the greater one came her way, and she showed increasingly in her private conduct a contemptuous disregard for Scots prejudices. Worse still, by claiming the English throne, Mary obliged Elizabeth to regard her as an acutely dangerous enemy and therefore to take every opportunity of diminishing her power.

Mary's second marriage was a consideration of paramount importance. She was ready to take any Spanish or French husband who would invade England on her behalf. Elizabeth, knowing this, told her that any such match would be regarded by England as a declaration of war. Mary, though prepared to take the English crown by force whenever a chance should offer, was at present only asking to be officially recognized as Elizabeth's heirress presumptive. She was told that if she accepted Elizabeth's favourite, Lord Robert Dudley (afterward earl of Leicester), as a husband whose alliance would threaten no danger to England, this status might be accorded her. Mary pretended to consider this proposal, in order to mask her real intention. She had determined to marry her cousin Henry Stewart, Lord Darnley (*q.v.*), who, descended from Margaret Tudor by a second marriage, had in Catholic eyes a claim to the English crown second only to Mary's own. Darnley's father, the earl of Lennox, who had been in England since 1544, was in Scotland on business connected with his Scottish estates and got leave from Elizabeth for his son to join him. Mary, it is safe to say, would have married Darnley whatever he had been like; actually, his great height and athletic grace and the

good manners he knew how to assume, charmed her into a brief personal liking for him. The match was approved by the king of Spain, who wanted the stronghold of Protestantism in England destroyed because its example menaced his government in the Netherland provinces. He promised (1565) that if Mary and Darnley would wait for a time convenient to him, he would support their invasion of England.

The prospect of a Catholic marriage for their queen alarmed the Scots Protestants, and Moray, who knew that Elizabeth must regard Darnley's defection as treason, feared the collapse of the Anglo-Scottish alliance. He attempted to arouse the citizens of Edinburgh against Mary's authority, but failed. Mary, who had married Darnley on July 29, 1565, probably at Holyrood, called to her side James Hepburn, earl of Bothwell (*q.v.*), an able soldier who had been a loyal servant of her mother. With a force which she led in person, she drove Moray and his supporters over the Border (in an action known as the "chase-about-raid"), proclaiming them outlawed, and their estates forfeit. The exiles took refuge in England, and Elizabeth, who had secretly encouraged Moray, reproached him in a public interview for taking arms against his sovereign.

Mary, exhilarated by her success, had declared publicly that she would lead her army to the walls of London. In a secret interview with the spy Christopher Rokeby, she told him that she was confident that the English Catholics would rise to support her. She meant with Spanish and papal help to create a disturbance in Ireland; then she would enter England at the head of her army and proclaim herself queen. She asked him meantime for a list of the English Catholics upon whom she could rely. Mary never understood how strongly Elizabeth's government was supported by England as a whole, and that the majority, even of the Catholics, did not want to see Mary on the throne at the expense of foreign invasion and civil war.

To her great misfortune, Darnley turned out to be a thoroughly bad bargain; stupid, arrogant and vicious, he soon forfeited even the tolerance of his wife. Mary showed her usual disregard of Scots feelings by the unwise familiarity with which she treated her Italian secretary David Rizzio, a lowborn man whom she allowed, because he was congenial to herself, to behave with insane presumption toward the haughty and vindictive Scots nobles. The nobles not only detested Rizzio for his conduct but also feared and loathed him because he managed Mary's correspondence with the pope. Darnley, treated with neglect and coldness by his wife, became jealous of Rizzio, and fell a prey to a conspiracy headed by his kinsman Lord Ruthven. The confederates made a pact with him that the exiled lords should be recalled and their estates restored to them. Rizzio should be put to death, the queen imprisoned and Darnley given the crown matrimonial. Darnley on his part signed an undertaking to protect the conspirators from the consequences of their deed, as the murder was done at his behest. His father Lennox went down to England to get the exiled lords to approve of the plan, thus joining them with the conspiracy.

The famous scene of Rizzio's murder, in Holyrood palace, when he was dragged shrieking from the queen's presence and dispatched with 56 stab wounds, took place on the night of March 9, 1566. Mary, who was six months' pregnant, behaved with brilliant courage and resource. Seducing her craven husband to her side again, she escaped with him out of the conspirators' hands and they fled to Dunbar. There Bothwell brought troops to her aid and she returned to Edinburgh surrounded by 2,000 soldiers.

Darnley denied all responsibility for Rizzio's murder, which so much enraged the exiles that they showed the queen the "band" (agreement) he had signed. Henceforward Mary regarded him with virulent contempt and loathing. A temporary reconciliation at the birth of her son James in June 1566 soon broke down. Shunned, humiliated and demoralized, the wretched young man threatened to leave Scotland, which would have caused an embarrassing scandal. Mary's pardon granted to the exiled lords and their return to Edinburgh filled him with apprehension, but what made his situation desperately dangerous was that Mary now succumbed to an infatuation for Bothwell. How soon or by what evidence this showed itself is disputed, and the authenticity of

some, at least, of the Casket Letters (*q.v.*) has been denied. These were a collection of verses and letters apparently written by Mary Stuart to Bothwell, and kept by him in a silver box. If "Letter II" be genuine, it proves Mary's passion for Bothwell and that she was in league with him to have Darnley murdered. The reason for believing her to be implicated in this design does not, however, rest on the authenticity of the Casket Letters, but on the presumptive evidence of her conduct.

In Nov. or Dec. 1566 she held a council at Craigmillar castle, near Edinburgh, in which she discussed with her nobles, including Maitland and Bothwell, the possibility of freeing herself from her odious husband. Maitland told her to leave it to them; they would find a means. In Jan. 1567 Mary visited Darnley who had developed an illness described as smallpox and was in the care of his father at Glasgow. Reconciling herself to him by a display of affection, she brought him back to Edinburgh, not to Holyrood lest he should infect their child, but to a half ruined house in the city wall (on the site of the present university buildings) named Kirk o'Field. There he was lodged on the upper floor while the queen slept in the room below. On the night of Feb. 9, Mary appeared suddenly to remember that she had promised to attend a wedding festivity at Holyrood. She departed by torchlight, sending back a page to bring away a rich coverlet from her bed. Between 2 and 3 A.M. a terrific explosion laid Kirk o'Field in ruins. Darnley and his page, it was concluded, had received the alarm and tried to escape. Their bodies were found strangled in the garden.

On the evidence of his comings and goings, public opinion immediately credited Bothwell with the deed, and placards denouncing him as the murderer were put up in the market place. Lennox demanded an immediate investigation. Mary temporized, but the outcry against Bothwell was so fierce that it was conceded he should stand his trial, not, however, in a prosecution by the crown but merely in a private action at the hands of Lennox. The latter was given no time to collect his witnesses, and when told that he must not bring with him more than 6 retainers, while 4,000 of Bothwell's men invested the streets of Edinburgh, he decided in self-protection not to attend the trial in person. Bothwell rode to the courthouse on Darnley's favourite charger, and the farcical trial at which no witnesses were called ended in a verdict of not guilty. Subsequently Bothwell, at a supper at Ainsley's tavern, told more than 20 nobles that the queen had consented to marry him, and produced a document asking her to reward his services with her hand, to which he demanded their signatures.

The period of royal mourning was a long one, so the queen and Bothwell devised a scheme to make their immediate marriage seem desirable. With her connivance, he waylaid her cavalcade as she traveled from Stirling to Edinburgh on April 24, 1567, and carried her off to Dunbar, of which she had made him castellan. On May 3 Bothwell's wife was given a divorce for his infidelities. On May 6 the queen and Bothwell returned to Edinburgh, where Mary announced that though Bothwell had handled her "roughly," she was convinced of his loyalty and good meaning toward her, and that she intended to grant the request of her nobles by marrying him. The minister of St. Giles' church published the banns only when Bothwell threatened to hang him for his refusal, and the wedding was celebrated with Protestant rites at Holyrood palace on May 15, 1567, three months and a week after Darnley's murder.

Every mistake that Mary had so far made, she might have lived down. Many of the lords were as deeply concerned in Darnley's murder as herself and had she been content merely to be rid of him and had she then resigned herself to the guidance of Moray, she might have had a second chance, but the Protestant lords would not endure to have Bothwell set over them. The risings against the Queen began less than a month after the marriage. On June 15, 1567, her forces were drawn up against those of the rebels on Carberry hill (Midlothian), but her men would not fight. On condition that Bothwell should be allowed to go free, she gave herself up to the lords, expecting them to return to their allegiance. The insults of the soldiers and of the mob in the Edinburgh streets shouting "Burn the whore," drove her to a frenzy of anger. Finding that she was attempting to communicate

with Bothwell, the lords moved her to the island fortress of Lochleven, where it has been said that she miscarried of a child or twins by Bothwell. The casket of letters fell into the hands of the lords on June 20, when it was captured from a servant whom Bothwell had sent to bring it from Edinburgh to Dunbar. After examining the contents, three lords went to Lochleven, where they offered Mary the choice between abdication or standing trial for murder. She signed a deed of abdication which she afterward repudiated, and her one-year-old son became King James VI of Scotland, with Moray as his regent. Just over nine months later she escaped from Lochleven and joined the marquess of Hamilton and his brother Claude (later Baron Paisley), who like the Lennoxes were descended from King James II and who were prepared to reinstate her that they might rule through her. Their forces were routed by Moray's at Langside, near Glasgow, on May 13, 1568, and Mary with a handful of followers fled through three days and nights to the shore of Solway. On May 16 she crossed the inlet and landed at Workington in Cumberland. Two days later she moved to Carlisle.

Captivity in England.—Mary's choice of England as a refuge rather than France was easily understood. The French court could not help her, for it was engaged in a religious civil war; and its attitude toward her had been shown when it sent no embassy of condolence on Darnley's death. Elizabeth had offered help when the rebellion began, and Mary meant now to claim it. She believed Elizabeth would not dare to withhold it from a fellow monarch against rebels, and she was further supported by her conviction that the English Catholics would acclaim her as their queen.

The situation in which Mary was a potential storm centre in her realm, and in which Mary and Moray were both appealing to her for help, was of the utmost complexity and danger for Elizabeth. While Mary was detained (July 13, 1568–Feb. 26, 1569) at Bolton castle in Yorkshire, Elizabeth set up an inquiry which was opened at York (Oct. 4, 1568) and afterward moved (Nov. 25) to Westminster, in the course of which Moray ultimately produced all the evidence against Mary's misgovernment and unofficially showed the commissioners the Casket Letters. Mary through her representatives declared that it was beneath her to make any defense. Her opponents were rebels, on trial for treason; it was for them to defend their conduct. This attitude she maintained for the rest of her life. When Mary had been publicly discredited by the production of Moray's evidence, Elizabeth closed the proceedings, saying Mary had not been proved guilty of complicity in the murder, and Moray had not been proved guilty of treason. The latter returned to govern Scotland. Mary was kept in England, ostensibly because Elizabeth had recognized Moray's regency; and his government (as it stated at the council of Perth in 1569) refused to have Mary back in Scotland even to live as a private person. Actually, considering what Sir William Cecil (afterward Baron Burghley) called "her appetite to the crown," Mary was too dangerous to let go. She was transferred to the keeping of the earl of Shrewsbury and was moved in Jan. 1569 to his castle at Tutbury in Staffordshire. For almost all the remainder of her life she lived in his various houses and castles, with a household of 30 of her own servants, her French dowry at her own disposal, and treated with the ceremony due to a queen. In Aug. 1584 Sir Ralph Sadler succeeded Shrewsbury as Mary's custodian, but was himself replaced by the cold and unbending Sir Amyas Paulet in Aug. 1585.

Apart from the mere want of liberty, her conditions were easy, but her insatiable ambition and lust for vengeance made them almost intolerable. She now embarked on 19 years of plotting to secure her freedom and to attain Elizabeth's throne. Of the three major plots in which her complicity was proved, each was based on the assassination of Elizabeth and the bringing over of a Spanish army from the Netherlands. The first of these began with the rising of the earls of Northumberland and Westmorland in 1569, whose aim was merely to marry Mary to the duke of Norfolk and restore the Catholic religion. The rebels marched toward Tutbury and Mary was removed (Nov. 25) to Coventry. When this rising had been put down, Norfolk was discovered in the much more serious plot of Roberto Ridolfi (*q.v.*), who was

trying to gain Spanish help in a scheme which was to begin with the murder of Elizabeth. Mary, who was moved in May 1570 to Chatsworth (Derbyshire) and in Nov. 1570 to Sheffield castle, was kept *au courant* with all the details and wrote to the Spanish ambassador in London: "Tell your master that if he will help me I shall be queen of England in three months." The discovery of the plot led to the execution of Norfolk (1572) and only Elizabeth stood between Mary and the demand of the houses of parliament that she should be put to death. The second large-scale conspiracy based on the murder of Elizabeth and an invasion known as "the Enterprise" was engineered by the duke of Guise, and was discovered in 1583 (see THROCKMORTON, FRANCIS). The third one came to light when Sir Francis Walsingham, who managed Elizabeth's secret service, devised a method of tapping Mary's correspondence and thus learned of plans for another invasion. Mary, who had returned to Tutbury early in 1585, was moved to Chartley castle, Staffordshire, in Jan. 1586. While she was there, Walsingham discovered that Mary was in communication with Anthony Babington (*q.v.*), the English agent of a conspiracy with the usual features, and that Babington had told Mary that Elizabeth's assassination was to be undertaken. When a reply from Mary of a compromising nature was in his hands, Walsingham accused her of conspiring to compass the death of the English queen.

She was brought to trial in the great hall of Fotheringhay castle (where she had been moved on Sept. 25) on Oct. 14-15, 1586. By modern standards the trial was unfair to the accused, and the courage and virtuosity with which Mary defended herself can but arouse sympathy and admiration; but evidence was brought against her which her mere denials did not outweigh. A verdict of guilty was returned, but it was more than three months before Elizabeth could be induced to sign the death warrant.

The execution was carried out in the great hall at Fotheringhay on the morning of Feb. 8, 1587. The memory of Mary's superb demeanour in the last hour of her life; her debonair courage; the graciousness with which she gave the headsman the pardon he knelt to ask; the memory of the tragic eclipse of her early brightness, and of the long endurance of her captivity, in the end effaced the significance of her actions and made her the heroine of a melancholy and thrilling romance. The interest of her story has never waned; it has those elements that are always found romantic. The fact that she ruined herself by uncontrolled sexual passion has brought her a host of sympathizers, as also has her unflinching energy and courage in the face of misfortune. The unwaning appeal of her story is perhaps explained by the combination of that story, full of bold action and secret motive, with the fact that though she lost the great stake for which she played, she never lost her courage and determination, and above all by her extraordinary personal charm, which survives death and time.

Mahon, *The Tragedy of Kirk o' Field* (1930), which contains a good bibliography. All general histories of the period contain much detail about Mary. (E. JE.)

MARY OF THE INCARNATION (BARBE JEANNE AVRILLOT, MME ACARIE) (1566-1618), French mystic who was also unusually active and influential in religious affairs and who in-

spired, if she did not direct, nearly all the French religious leaders of her day, was born in Paris on Feb. 26, 1566, the daughter of a wealthy bourgeois family. She early showed signs of exceptional piety and wanted to enter a convent, but in obedience to her parents she married Pierre Acarie, vicomte de Villemore in 1582 and became a model wife and mother of six children. Mme Acarie, who wrote nothing and died in her early 50s, was instrumental in introducing into France the Discalced Carmelites founded by St. Teresa of Ávila; she worked for the expansion of the Ursulines; she encouraged Pierre de Bérulle in founding the Oratory; and the reform of the Benedictine convents in France owed much to her. After the death of her husband (1613), Mme Acarie was received as a lay sister in the Carmel at Amiens and was professed in 1615 as Mary of the Incarnation. She transferred in 1616 to Poitiers to reform the finances of that convent, where she died on April 18, 1618. She was beatified in 1791 (feast day April 18).

Blessed Mary of the Incarnation was an ecstatic visionary in whom her contemporaries found a perfect type of that sublime life to which many souls of the time felt themselves called. Her message was based on the statement of the Gospel "The kingdom of God is within you," interpreted in a mystical sense.

MARY OF LORRAINE (MARY OF GUISE) (1515-1560), was regent of Scotland for her daughter, Mary Stuart, during the critical early years of the Scottish Reformation, and was born at Bar-le-Duc in Lorraine on Nov. 22, 1515, the eldest child of Claude, duc de Guise. By her first marriage, to Louis d'Orléans, 2nd duc de Longueville on Aug. 4, 1534, she had one son, François, 3rd duc de Longueville. Widowed in 1537, she was sought in marriage by Henry VIII of England and James V of Scotland. The latter married her by proxy in France and in a second ceremony at St. Andrews, soon after her arrival in Scotland in June 1538. Their infant sons, James and Arthur, both died in 1541 and the king himself died on Dec. 14, 1542, a few days after the birth of their daughter, Mary (*q.v.*) Stuart. Though the earls of Bothwell and Lennox both aspired to be her third husband, Mary's chief ambition was to oust the heir presumptive, James, 2nd earl of Arran (see ARRAN, EARLS OF), from the regency. The question of her daughter's marriage also complicated Scottish politics. A council, of which Mary of Lorraine was the principal member, was appointed to direct the regent in Sept. 1543, but her attempt to supersede Arran in 1544 was unsuccessful. Nevertheless, the death of Cardinal David Beaton on May 29, 1546, left her as the leading figure in Scotland.

The conclusion of peace with England in 1550 enabled Mary of Lorraine to visit her children in France, where Mary Stuart had been sent in 1548, and on her return journey she also visited Edward VI of England. In a further unsuccessful attempt to induce Arran to resign the regency, she persuaded the French king to confirm the duchy of Châtellerauld (Châtellerauld) to him, but Arran insisted on his right to retain office until the queen completed her 12th year. However, he resigned in a parliament held in Edinburgh on April 12, 1554, and Mary of Lorraine took his place. At first her rule was successful and beneficial, despite resentment at the introduction of Frenchmen into the high offices of state. She had to withdraw a proposal for a standing army and the Scottish nobles refused to invade England in 1557. To offset Arran's power, she had to rely on the anticlerical lords and show favour to the Protestant preachers with whose support she arranged her daughter's marriage in 1558 to the dauphin (later Francis II of France). Apparently under pressure from France, the regent abandoned her policy of toleration and attempted the suppression of Protestantism in Scotland. Legal proceedings against a number of preachers in 1559 led to an uprising at Perth, in which the mob sacked churches and religious houses. Civil war was averted temporarily by an agreement, which the lords of the congregation then asserted the regent to have broken, by garrisoning Perth with Scottish troops in French pay. Reassembling their

forces they drove Mary from Edinburgh and on Oct. 21, 1559, issued a proclamation that she had been deposed. Although hampered by the defection of Châtelherault, his son, James, 3rd earl of Arran, and her secretary, William Maitland of Lethington, Mary and the French defended Leith and recaptured Edinburgh. An English army helped the Protestants by laying siege to Leith in April 1560. The ailing regent took refuge in Edinburgh castle and on her deathbed summoned the nobles of both parties, urging them to dismiss the armies of France and England and to return to their allegiance to her daughter. She died on June 11, 1560, and in March 1561 her body was taken to France for interment in the abbey of St. Pierre at Reims.

The historian, John Leslie, described Mary of Lorraine as "a noble, wise and honourable princess and chaste lady, ever well and virtuously employed," a character more credible than John Knox's malicious slanders against her. Although mindful of French and family interests, she was equally solicitous for the welfare of Scotland. It was her misfortune, rather than her fault, that her regency ended in civil war and foreign invasion.

MARY OF MODENA (MARIE BEATRICE D'ESTE) (1658-1718), queen consort of James II, king of Great Britain, and daughter of Alfonso IV, duke of Modena, and the duchess Laura, of the Roman family Martinuzzi, was born at Modena on Oct. 5 (new style; Sept. 25, old style), 1658. She was married by proxy to James, then duke of York, on Sept. 30 (N.S., 20 O.S.), 1673, and reached England in November. By the public she was regarded as an agent of the French and papal interests, but her influence on her husband's political or religious thinking appears to have been negligible. At court she was popular enough, and on terms of intimate friendship with her elder stepdaughter, the future Mary II. But between 1675 and 1682 she bore five children, none of whom survived, and when her second son, James Francis Edward, was born on June 10 (O.S.), 1688, it was widely rumoured that the child was not really hers but had been imposed on the nation to insure a Catholic succession. This was ostensibly the principal reason for William of Orange's coming to England that autumn. At the outbreak of the revolution, Mary made the mistake of consenting to escape to France with her son (Dec. 20, 1688). She urged James to follow when it was to his manifest interest to stay in England, and when he went to Ireland in 1689 she pressed for his return. Another child, Louisa Maria, was born to her at St. Germain on June 28, 1692. Her influence over her husband increased markedly in their exile. She survived him by 17 years, at St. Germain and at Chaillot, in a house of the Visitation, where she died on May 7, 1718.

(J. P. K.)

MARY OF TECK (1867-1953), queen consort of George V of Great Britain, was born at Kensington palace in London on May 26, 1867. She was the eldest child of Francis, prince (later duke) of Teck, of the royal house of Württemberg, and of Princess Mary of Great Britain, a granddaughter of George III. After spending her early years in London, she lived in Florence from the age of 16 to 18 and there acquired a taste for the arts which was to distinguish her throughout life. In 1891 she became engaged to the elder son of the prince of Wales, the duke of Clarence, who died a few weeks before the marriage was to have taken place. A year later her engagement was announced to the duke's younger brother, afterward George V. They were married on July 6, 1893. As duchess of York (during Queen Victoria's reign) and princess of Wales (during Edward VII's reign) she was active with her husband in a variety of public duties, including a journey to Australia in 1901, for the opening of the federal parliament, and a long tour in India during 1905.

With the accession of King George in 1910 she became queen, and brought to her high position gifts of taste and intellect that quickly made their mark on court life. Her bearing showed how accurate Queen Victoria had been when she wrote that May (the name by which Queen Mary was known in the family circle) was so sensible and *distinguée*. Her good taste showed itself in the

mastery of the royal collections and her concern that they should be displayed to the best advantage. In the 1920s she encouraged the publication of an account of the inside of Buckingham palace. During World War I the queen was especially concerned with the welfare of servicemen and with nursing and after the war appeared increasingly in public, particularly after the decline of the king's health in 1928. His gratitude to her was expressed in his speech in Westminster during his silver jubilee in 1935, and the king asked that that passage be placed last in the speech because he was afraid that he might be overcome "when I think of all that I owe her."

In widowhood the queen moved to Marlborough house. To her eldest son, King Edward VIII, she was singularly devoted, and his abdication was a severe test of her courage. During World War II she retired to Badminton, the home of her niece, the duchess of Beaufort. She became a familiar figure in the west country, visiting bombed towns and service centres and delighting in giving lifts to soldiers and airmen in her car. In 1945 she resumed her life in London. Her health began to fail after the shock of the death of King George VI in 1952 and although she attended his lying in state in Westminster hall she was thereafter seldom seen in public. She died at Marlborough house on March 24, 1953.

Although Queen Mary in her dress and manner retained something of the habit of the Victorians—she never made a speech in public and never spoke on the telephone—her spirit moved with the times, and this helps to explain her popularity with all classes. She had five sons—King George VI, the duke of Kent and Prince John, who predeceased her, and the dukes of Windsor and Gloucester, who survived her—and one daughter, the princess royal.

See J. Pope Hennessy, *Mary, Consort of George V* (1960).

(R. T. B. F.)

MARY (1457-1482), duchess of Burgundy from 1477, whose marriage has been called the most important in history, was born in Brussels on Feb. 13, 1457, the daughter of Charles the Bold (q.v.), later duke of Burgundy, and his wife Isabelle de Bourbon. Many princes were willing to marry her for the Burgundian succession; and in 1476 it was finally agreed that she should marry the archduke Maximilian, heir to the Habsburgs of Austria (see MAXIMILIAN I, Holy Roman emperor). Charles, however, was killed at Nancy on Jan. 5, 1477, whereupon Louis XI of France sent his armies into the duchy of Burgundy, Franche-Comté, Picardy and Artois. Mary summoned the estates-general of her dominions to Ghent, but had to grant them the *Grand Privilege* of Feb. 11, 1477, whereby her predecessors' work of centralization was undone; and on April 3, two of her ministers, Guillaume Hugonet and Guy d'Humbercourt, were executed. Louis XI meanwhile was demanding the marriage of Mary to his son, the future Charles VIII of France; but Maximilian sent his proxy to marry Mary at Bruges on April 21 and married her in person at Ghent on Aug. 18. Through this marriage Franche-Comté, Artois and the Netherlands eventually passed to the Habsburgs; and the elder son of it, Philip the Handsome (1478-1506), was later married to Joan, heiress to Castile and Aragon, so that Spain also came to the dynasty. Mary died in Bruges on March 27, 1482, after a fall from her horse. See HABSBURG; NETHERLANDS, THE: History.

See L. Hommel, *Marie de Bourgogne, ou le Grand Héritage* (1951).

"MARY CELESTE," a 282-ton U.S. brig that sailed from New York city on Nov. 5, 1868, and was later found mysteriously abandoned. Aboard the vessel when it sailed from New York were Capt. B. S. Briggs, his wife and daughter, and a crew of seven. "We enjoy our melodeon and have some good songs," wrote the captain before leaving. This was the last ever heard from any of those on board. A month later the "Mary Celeste" was sighted off the Azores by a British craft. Receiving no response to her signals, the British vessel sent a boarding party to investigate. It found the "Mary Celeste" deserted but in excellent shape except for weather damage. The log was on the mate's desk, the pantry was intact and the melodeon was unharmed. Why the ship was abandoned has never been satisfactorily explained. One theory is based on the fact that the ship had a cargo of alcohol. Perhaps Captain Briggs opened a hatch that had been closed for several days and was blasted by outrushing gases. Frightened into a panic, every-

one crowded into the lifeboat, with a line to the "Mary Celeste." Their boat capsized, drowning all. This theory is supported by the fact that the lifeboat was missing and a fragment of line dangled from the stern of the "Mary Celeste." (F. O. Br.)

MARY IMMACULATE, OBLATES OF (CONGREGATIO MISSIONARIORUM OBLATORUM B.M.V. IMMACULATAE; O.M.I.), one of the largest missionary congregations of the Roman Catholic Church, was inaugurated at Aix-en-Provence, France, on Jan. 25, 1816, as the Missionary Society of Provence by Charles Joseph Eugène de Mazenod (1782-1861), later bishop of Marseilles. By preaching to the poor, Mazenod wished to counteract the irreligion resulting from the French Revolution. On Feb. 17, 1826, Pope Leo XII approved the society as a religious congregation. Its members (numbering over 7,500) bind themselves to common life by the simple vows of poverty, chastity, obedience and perseverance. A superior general in Rome directs activities on every continent. Where the church has been long established, the task of this congregation is to strengthen the faith, especially by preaching parish missions and retreats, teaching and directing national shrines. Pioneering missionary efforts in Africa, South America, the orient and the arctic have been among its most important works.

(G. F. McL.)

MARYLAND, one of the 13 original states of the United States, extends along both sides of Chesapeake bay on the Atlantic coast. It is bounded on the north by Pennsylvania; on the east by Delaware, the Atlantic ocean and a small section of Virginia; on the south and west by the District of Columbia and the Potomac river; and on its extreme west by West Virginia. In area it ranks 42nd among the states, having a total area of 10,577 sq.mi., of which 9,874 sq.mi. are land, 703 inland water excluding 1,726 sq.mi. of the Chesapeake bay. In population it ranks 21st among the states, with 3,100,689 inhabitants in 1960. Since 1694 Maryland's capital city has been Annapolis, which is also the seat of the U.S. Naval academy and St. John's college. Baltimore, a thriving port on Chesapeake bay, is the state's largest city.

Maryland was named in honour of Queen Henrietta Maria, wife of Charles I of England, who granted the territory to Lord Baltimore (Cecil Calvert) on June 20, 1632. It is popularly known as the "Old Line state" because of the distinguished service of Maryland's regular "troops of the line" during the American Revolution. The state flower is the black-eyed Susan, the state bird the Baltimore oriole, and the state tree the white oak. The state flag is a colourful one, bearing the arms of both the Calvert family and the Crosland family, to which the mother of the first Lord Baltimore belonged.

"Maryland, My Maryland" is one of the best known of all state songs. The words, written in 1861 by James Ryder Randall, a Marylander living in the south, are sung to the German tune "O, Tannenbaum." The national anthem was written in Maryland by another Marylander, Francis Scott Key (*q.v.*), while Fort McHenry was under attack during the War of 1812.

PHYSICAL GEOGRAPHY

Physical Features.—Maryland, which lies between approximately 37° 53' and 39° 43' N. and approximately 75° 4' and 79° 29' W., possesses a great diversity of surface features. It is crossed from north to south by each of the leading topographical regions of the eastern portion of the United States—the coastal plain, the piedmont plateau and the Appalachian system. The part within the coastal plain includes nearly all of the southeastern half of the state and is commonly known as tidewater Maryland. It is marked off from the piedmont plateau by the fall line, a zone in which a descent of about 100 ft. or more occurs in many places within a few miles, creating waterfalls and rapids in the streams. The fall line extends northeast from Washington, D.C., through Baltimore to the northeast corner of the state. Chesapeake bay divides the coastal plain into two main sections: all of Maryland east of the bay and south of the Elk river is known as the eastern shore; the western shore or "Maryland main" extends westward from the bay to the fall line.

The eastern shore is a low, level plain, rising northward to a

height of only about 100 ft. above sea level. Along its Atlantic coast extends the narrow sandy Sinepuxent beach, formerly enclosing the Sinepuxent bay on the north and Chincoteague bay on the south. A storm in the 1930s cut an opening into Sinepuxent bay at Ocean City, making available a fine harbour for fishing fleets and other boats at the seaside resort. The eastern shore is drained by the Northeast, Elk, Sassafras, Chester, Miles, Tred Avon, Choptank, Nanticoke, Wicomico, and Pocomoke rivers. It is connected with the western shore by the Chesapeake bay bridge.

The western shore is somewhat more undulating and higher than the eastern shore, sloping generally from northwest to southeast. Along the western border are points 300 ft. or more above sea level. The Patuxent and Potomac are the principal rivers crossing this section, but the Severn, Magothy, Patapsco, Gunpowder and Bush rivers also drain it.

The piedmont plateau or foothill region extends west from the fall line to the crest of the Blue Ridge mountains. In general, it has a broad rolling surface and rises gradually to heights of over 1,000 ft. Its principal streams wind their way toward the southeast in narrow steep-sided gorges and broad limestone valleys.

Appalachian Maryland lies in the area extending from the crest of the Blue Ridge mountains to the western boundary of the state. It includes most of Washington and Allegany counties. To the eastward it abounds in mountains and valleys but is a rolling plateau in the extreme western portion. Antietam creek to the east and Conococheague creek to the west flow through its eastern portion in trenches that in places exceed 75 ft. in depth.

The Appalachian ridges of the western portion begin with North mountain on the east and end with Wills mountain on the west. Overlooking these ridges are the higher ranges of the Alleghenies among which the Savage, Backbone and Negro mountains reach elevations of 3,000 ft. or more. The highest peak in the state is Backbone mountain (3,360 ft.) in Garrett county. Located in the extreme western part of the state, these mountains merge into the rolling Appalachian plateau. The mean elevation of the state is 350 ft. All rivers of western Maryland flow south into the Potomac except the waters of the Youghiogheny and its tributaries in the extreme west, which flow into the Monongahela.

Chesapeake bay is 193 mi. long, with 115 mi. in Maryland and 70 mi. in Virginia. It is from 2.6 to 25 mi. wide and is navigable for ocean-going ships. It has two outlets to the Atlantic ocean, one through the Chesapeake and Delaware canal built at the northern end of the bay in 1829, and the other through the mouth of the bay between the Virginia capes.

Climate.—The Atlantic ocean, Chesapeake bay and Appalachian mountains greatly influence the climate of Maryland. Prevailing winds are westerly—generally northwesterly in winter in the western section and southwesterly in summer in the southern area. In the south the winter is usually mild and the summer rather hot; in the west the winter is usually cold, the summer cool. The normal average annual temperature for the entire state is between 53° and 54° F. (about 12° C.). The average precipitation is about 43 in. (1,100 mm.).

Soil.—Maryland has a great variety of soils that provide rich farmland in most of the coastal and piedmont regions. The upper eastern shore has a light marly loam while the lower area has a stiff soil with light-coloured clay. In southern and central Maryland, sandy and tidal marsh loam prevails. Along the lower edge of the fall line is a belt so heavy with clay that it is of little agricultural value. Soils of the eastern piedmont plateau are variable but most are heavier with clay than those of the coastal plain and better for general agriculture. Limestone and sandstone provide the soil in the western piedmont area. Much of the far western part of the state is too rugged for agriculture.

Vegetation.—The state's 2,900,000 ac. of forested areas are mostly farm woodland or other private holdings. They comprise about 46% of the land surface, but contain virtually no virgin timber. The state administers 12 state forests with a total area of approximately 120,000 ac. There are about 150 species of trees in the state, including black and white oak, beech, poplar, locust, hickory, ash, gum, elm, spruce, hemlock and dogwood. The most numerous types are pine and oak; chestnut and walnut have

become rare. Blackberry and raspberry bushes are common in some areas. Wild flowers include roses, goldenrod, honeysuckle, trailing arbutus, mountain laurel, azalea and violets.

Animal Life.—Occasional bobcats and bears are the state's most imposing animals in the mountainous areas, while deer, foxes, opossums, raccoons, squirrels, chipmunks and rabbits may be found elsewhere in the state. The copperhead and the timber rattler are the only poisonous snakes. The Japanese beetle and the 17-year locust are among the most destructive insects.

Wild ducks and geese of many kinds abound in the Chesapeake bay area in season. The Chesapeake bay retriever, used for hunting water fowl, is native to the state. Game birds found in the inland regions include quail, partridge, wild turkey and ruffed grouse. Songbirds are plentiful, especially Baltimore orioles, thrushes, finches, warblers and whippoorwills. Hawks, bald eagles, herons and owls are fairly common.

The Chesapeake bay and coastal waters contain some 200 species of fish and large quantities of oysters and crabs. Both commercial and sports fishing are important.

Historic Sites, Parks and Forests.—Maryland has many attractions for persons interested in early U.S. history. Annapolis, the site of the oldest state capitol in continuous use, has more original colonial buildings standing than any other city in the United States. Here also are St. John's college, established as a secondary school in 1696; the United States Naval academy dating from 1854; and such splendid examples of colonial architecture as the Hammond-Harwood house and the Chase home.

Doughoregan Manor in Howard county and Homewood in Baltimore were built by Charles Carroll of Carrollton, a signer of the Declaration of Independence. The homes of Roger B. Taney, famed chief justice of the United States, and of Barbara Fritchie, a Union patriot, are in Frederick. Antietam National battlefield and National Cemetery in Washington county are dedicated to soldiers of that Civil War battle. Near Boonsboro stands the rough stone monument, now restored, erected on July 4, 1827, in honour of George Washington. The Washington monument in Baltimore was completed in 1829 in modified form. Fort McHenry and Mount Clare station, the first railroad passenger and freight station to be erected in the United States, are in Baltimore. (See BALTIMORE.)

The eastern shore abounds in historic sites. At Chestertown in Kent county is Washington college, Maryland's oldest. It was founded in 1782 by the Rev. Dr. William Smith. George Washington contributed financially and gave the use of his name. In Kent county also is St. Paul's church, dating to the late 17th century. At Easton in Talbot county is Third Haven meeting house, built by the Quakers in 1682-83 and said to be the oldest frame structure for worship in the United States. A replica of the original capitol of the colony has been built at St. Mary's City on the St. Mary's river about 6 mi. N. of Blakistone Island. Tours of these and other historic sites are conducted annually.

Maryland has more than 25 state parks, state forests and recreational areas, including ocean beaches, bay shore, dense forests and mountains. Their total area is nearly 150,000 ac. Among the better known state parks are Elk Neck, Fort Frederick, Gambrill, Patapsco, Sandy Point and Washington Monument. Camp David is located in the Catoctin Recreational Demonstration area, a federal project near Thurmont. Ocean City is a popular summer resort on the Atlantic coast.

HISTORY

Establishment and Early History.—The colony of Maryland owed its existence to George Calvert, first Lord Baltimore, who petitioned for a charter from Charles I of England in 1632. (See BALTIMORE, GEORGE CALVERT, 1st Baron.) A man of stature and high position, Calvert had been converted to Roman Catholicism and desired, among other things, to establish a haven for the Roman Catholics. Earlier, he had attempted without success to found a colony at Avalon, Newfoundland.

George Calvert died in 1632 before the charter was sealed. The king then made the grant to Calvert's oldest son, Cecil, second Lord Baltimore. The charter, which granted to Calvert the ter-

ritory that lay between the Potomac river and the 40th parallel, also granted him broad powers and extensive rights such as were not conferred upon any other single proprietor. Nearly 200 colonists sailed from England in the "Ark" and the "Dove" in Nov. 1633, under the colony's first governor, Leonard Calvert, brother of the proprietor. They reached Maryland four months later, landing first at St. Clement's Island (now Blakistone Island) on March 25, 1634.

The colony was launched under favourable circumstances. For more than 60 years it centred around St. Mary's City. There was no great trouble with the Indians, no period of starvation or widespread disease and the climate was not severe. Maryland was well planned and profited from the experience of earlier colonies. Difficulties, however, arose with William Claiborne and other Virginians who regarded the Marylanders as trespassers upon soil originally granted to Virginia. Claiborne was interested in personal possession of Kent Island on the eastern shore where he had established a trading post and claimed also to have cultivated the soil. A phrase in the Maryland charter, *hactenus inculta*, permitted Lord Baltimore to settle only territory that had not hitherto been cultivated. A series of petty conflicts, invasions and naval battles ensued. Claiborne was eventually dispossessed of Kent Island in 1638 when ruled against in England, but he remained a thorn in Maryland's side for several decades. Richard Ingle, a vigorous partisan of parliament, also offered trouble and temporarily seized St. Mary's City in the mid-1640s.

Maryland's Act Concerning Religion, passed by the assembly in 1649 and usually called the Toleration act, was a pioneer statute and gave Maryland claim to being the first civil regime in America to recognize freedom of conscience. From the beginning Marylanders had a large measure of freedom of conscience and the proprietor had endeavoured to separate church and state in the colony. Although the Toleration act limited tolerance to Christians, the record is bare of any persecution of Jews. However, with Cromwell seated firmly in England, zealous Maryland Puritans swept away toleration in 1654 when Lord Baltimore was deprived of his government and Anglicans, Catholics, Jews and all dissenters were placed under disabilities as oppressive as any imposed in America.

The return of Charles II to the throne in 1660 and the re-establishment of Lord Baltimore's government inaugurated a period of surface tranquillity in Maryland that lasted for nearly 30 years. The proprietor's position was stronger despite the ordeal through which he had passed under the Commonwealth. The period 1660-89 witnessed the settlement of new areas along the Chesapeake bay and the principal rivers. Most of the great estates as well as the smaller plantations shipped their produce from their own wharves. All land was held feudally, each 100 ac. having a quitrent of four shillings imposed on it.

Despite surface quiet, a constitutional revolution was developing. It involved a conflict between the governor and his council on the one hand and the lower house representing the voters on the other. In essence, it was the proprietary party versus the popular party, the rights of the proprietor set against the rights of the people. Through his appointments, the proprietor was generally able to hold the upper hand. He had tactfully surrendered his claim to the sole right of initiating legislation in 1638. With opposition mounting, however, Gov. Charles Calvert foolishly sought to strengthen the government by disfranchising all freemen who possessed less than 50 ac. or a personal estate of less than £40 sterling. The right to vote was thus limited to freeholders and was taken away from freemen. The plan of representation in the assembly also became the subject of heated controversy. Resistance in Charles and Calvert counties plus Indian molestations harassed the proprietor. Further, he was accused of prejudice against Roman Catholics and of resistance to royal customs collectors.

While Lord Baltimore sought to defend himself in England, boundary disputes flared in Maryland. The first involved the Maryland-Virginia line across the Potomac river and the Chesapeake bay to the mouth of the Pocomoke river on the eastern shore. This line was not clarified until 1785 and revised in 1871.

The other dispute was the bitter and prolonged one between the Baltimores and Penns over the Maryland-Pennsylvania boundaries and the boundaries of Delaware, which had originally been a part of the Maryland grant. In 1682 England transferred it to the Duke of York and in 1685 it was denied to Lord Baltimore on the grounds that Christians had inhabited it before the Maryland grant was made. After decades of disagreement and litigation, the fifth Lord Baltimore (the second Charles Calvert) came to an agreement with the sons of William Penn. For reasons unknown, except possibly ignorance of the facts, he surrendered his claims to the three lower counties (Delaware). He also relinquished Maryland's northern boundary, specified in the charter as the 40th parallel, which ran north of Philadelphia, and agreed to a line 15 mi. S. of Philadelphia. When he realized his error, Lord Baltimore repudiated his agreement but after more years of bickering, it was held binding in 1750 by Lord Chancellor Hardwicke, who ruled that original boundaries were too uncertain to be relied upon. Frederick, the sixth Lord Baltimore, refused to accept the chancellor's decision until 1760. Finally, after surveys by Charles Mason and Jeremiah Dixon between 1763 and 1767, the line was fixed at the parallel $39^{\circ} 43' 19.9''$. At one point the distance between this line and the Potomac river, the state's southern boundary, is less than two miles.

In England Lord Baltimore was charged with mismanaging the customs situation. To make matters worse, in Baltimore's absence, the acting governor had murdered the royal customs collector. This and other problems—insurgent uprisings, poverty, religious friction, the uncertainty of the tobacco trade and the bothersome use of tobacco as a medium of exchange—led to the overthrow of proprietary government in Maryland in 1692. A royal government was established which allowed the proprietor to retain only his land rights.

The end of the 17th century saw the capital moved from St. Mary's City to Annapolis near the mouth of the Severn river on the western shore in 1694 and an act passed which led to the establishment of King William's school in Annapolis, the third oldest of its kind in the colonies. Eleven counties had been established. The chief commerce was in tobacco and the landed gentry were strong. During the royal period the Anglican Church was established as the official church in Maryland, supported by the taxpayers. The period saw an increase in the powers of the lower house as the assertion of liberty was finding expression. The royal period ended in 1715 when the fourth Lord Baltimore, Benedict Leonard Calvert, who had renounced Roman Catholicism, had full proprietary rights restored to him.

Following the Restoration and until about 1765, Maryland was generally well governed. The colony was not drawn heavily into the French wars, experienced only sporadic warfare with Indians and was left alone by England to manage its own affairs. However, there was no end to disputes as Maryland's distinguished lawyers were opposing proprietary prerogatives and insisting upon the privileges and rights of a free people. Daniel Dulany led the fight for the extension of English statutes to the colony. The proprietor contended that only those statutes directly mentioning the dominions were in force there.

There were numerous points of difference and most of them were economic at base. The agricultural classes attacked the privileged classes—the lawyers, the clergy and officers of state—many of whom were also large landowners. Fees and salaries came in for special criticism. The limitations of the one-crop tobacco economy in Maryland were always pressing. The paper currency act of 1733 provided a second medium of exchange to supplement tobacco and also helped to diversify the Maryland economy and finance the colony's share of the French wars.

The American Revolution.—After gaining a victory over France in 1763, Great Britain tightened the reins upon the colonies. Debts to British merchants, the lack of a proper colonial currency and taxes on imports led Maryland citizens to action. When the Stamp act of 1765 was imposed, Maryland cited the charter rights which exempted the colony from all taxes except those imposed by the colonial assembly. Resistance with other colonies helped define the colony's ideas of popular liberty, the rights of English-

men and clarified its attitude toward England.

The Boston Tea Party of 1773 had its counterpart in Maryland when a tea ship, the "Peggy Stewart," was burned in Annapolis harbour on Oct. 19, 1774. The Association of the Freemen of Maryland on July 26, 1775, one year before the Declaration of Independence, passed resolutions protesting against British practices and asserting colonial rights. The revolutionary movement in Maryland was led principally by the group that had fought proprietary prerogatives; it consisted of men of wealth and social position as well as those learned in the law. On the other hand, Maryland had a large body of loyalists, especially on the eastern shore.

Statesmen of Maryland played leading roles in both the first and second continental congresses and in signing the Declaration of Independence, while the colony's troops and individuals distinguished themselves in the war that followed. The first state constitution, adopted in Nov. 1776, replaced the colonial charter. It was far from democratic by modern standards. It established property qualifications for voting which were not abolished until 1810. The Maryland general assembly refused to ratify the Articles of Confederation when they were adopted by congress in 1777, holding out until 1781 when other colonies agreed to surrender to the federal government their claims to western land.

Problems of Independence.—Postwar problems included the disposition of confiscated loyalist property, the struggle for paper money and debtor relief. Maryland's controversy with Virginia over the use of the Potomac and lower Chesapeake bay resulting in the compact of 1785 was a step leading toward the constitutional convention. Such was also the Annapolis convention (*q.v.*) of 1786 at which, however, Maryland was not represented. Luther Martin distinguished himself as a representative of Maryland at the Philadelphia convention of 1787. Maryland ratified the constitution on April 28, 1788, and became the seventh state to do so. It also ceded territory and advanced money for public buildings to help form the District of Columbia (1791).

As a member of the union, Maryland was confronted with questions of slavery, agriculture, education, religion and others which required diligence and wisdom in their solution. The constitution of 1776 allowed free Negroes to vote for members of the lower house of the legislature, but this privilege was canceled by an amendment in 1810. The Napoleonic Wars adversely affected the state's commerce and during the War of 1812 Maryland was the scene of several engagements, at Havre de Grace, Caulk's Field in Kent county, Bladensburg and at Baltimore.

After 1815, Maryland was absorbed in its own problems but still active in the affairs of the nation. The national road was completed to the Ohio river in 1818, and 11 years later the Chesapeake and Delaware canal was opened. In 1829 work was begun on the Baltimore and Ohio railroad and the Chesapeake and Ohio canal. The state suffered severely in the depression of the 1830s.

Civil War and Reconstruction.—In 1860, as the Civil War approached, Maryland was a sharply divided state for it had social, economic and political ties with both North and South. Its population included approximately 87,000 Negro slaves and 84,000 free Negroes. As the state's geographical position made its adherence to the Union a necessity, President Lincoln and the military authorities prevented its secession by suspending the writ of habeas corpus, establishing martial law, controlling elections, suppressing pro-Southern newspapers and by making arbitrary arrests and imprisonments. Members of the legislature were arrested and imprisoned to prevent steps that might lead to secession. The majority of the people were Union sympathizers but opposed coercion of the South. The state was invaded several times during the war. (See AMERICAN CIVIL WAR.) Frederick was occupied by Lee's forces, and the battles of South Mountain, Monocacy and the crucial engagement at Antietam (*q.v.*), were fought with heavy loss. In 1864 Maryland adopted its third constitution; it freed all slaves in the state and provided an iron-clad loyalty oath. Lincoln, whose vote in the state was negligible in 1860, carried the state in 1864.

Problems of education and the administration of justice characterized the period of self-reconstruction in Maryland. The Demo-

cratic party regained power and held dominance for many years but did little before the turn of the century to effect civil service reforms, ballot reform and stricter corporation control. There was a boom in industry and commerce, with rail and water facilities increasing. Large philanthropic gifts were made by George Peabody for a conservatory of music, Johns Hopkins for a hospital and university and Enoch Pratt for a library.

Two-party government was restored in 1896 when the Democratic Gorman-Rasin machine was defeated. A period of extreme conservatism followed, but even the Baltimore fire of 1904 (*see* BALTIMORE) did not retard economic development. The Progressive movement in Maryland was expressed in the administration of Gov. Austin L. Crothers, 1908-12, when a direct primary law, an improved corrupt practices act, a good roads bill and the important Public Utilities commission act were passed.

20th Century.—In the 20th century, shipbuilding and steel manufacturing replaced the manufacture of men's clothes, boots and shoes as chief concerns. Agriculture progressed but the seafood and fisheries industry began to decline because of inadequate conservation measures due in part to the continuing boundary disagreement with Virginia over the Potomac river and Chesapeake bay. In 1956 the Maryland legislature abrogated the compact of 1785 and Virginia carried the matter to the U.S. supreme court. On Dec. 20, 1958, representatives of the two states signed an agreement to set up a commission to regulate the removal of oysters from the Potomac river and thus put an end to the so-called oyster war between the two states. The Maryland legislature, however, refused to ratify the agreement.

Among the notable military, naval and air force establishments in the state are the U.S. Naval academy, Aberdeen Proving Ground, Ft. George G. Meade, the Army Chemical centre, the Naval Ordnance laboratory, the Naval Medical centre and Andrews air force base. Among noted civilian government establishments in Maryland are the National Institutes of Health in Bethesda and the Agricultural Research centre at Beltsville.

Throughout the 1920s, and until 1935, the governor of Maryland was Albert C. Ritchie, a Democrat, who served for four terms. He won national acclaim for his administrative ability, for his opposition to prohibition and for various steps he took to improve the efficiency and economy of the state government.

A notable post-World War II development was construction of the Chesapeake bay bridge from the mainland to Kent Island and the Eastern Shore. William Preston Lane, Democratic governor from 1947 to 1951, laid the groundwork for this project and also instituted the retail sales tax that aided greatly in coping with the state's fiscal problems and he extended its road-building program. Gov. Theodore Roosevelt McKeldin, his successor, saw many of these projects through to completion and inaugurated others. The Baltimore harbour tunnel was opened in Nov. 1957. As the fourth Republican governor since 1860, McKeldin served two terms and greatly expanded state services. In the election of 1958 McKeldin was succeeded by the Democratic candidate, J. Millard Tawes, re-elected in 1962. The state's fifth Republican governor since 1860, Spiro T. Agnew, was elected in 1966.

GOVERNMENT

Maryland is governed by the constitution of 1867 which succeeded constitutions of 1776, 1851 and 1864. This constitution gave the governor increased powers, including a veto over acts of the legislature, called the general assembly. This veto may be overridden by a three-fifths vote of the members of each house. The governor is elected by popular vote for a four-year term. An amendment adopted in 1948 limited the governor, henceforth, to two terms. Maryland has no lieutenant governor. A vacancy in the governorship is filled by the legislature, with the president of the senate serving during the interim. The constitution may be amended by a three-fifths vote of all members of each house of the legislature and a majority of votes cast in a state referendum.

The constitution of 1867 established a general assembly consisting of a senate of 29 members and a house of delegates of 123 (later 142) members, all serving four-year terms. After the U.S. supreme court ruled (March 26, 1962) that metropolitan residents

were entitled to court hearing of complaints against denial of representation in legislatures, the assembly increased house membership from 123 to 142, with the new seats going to the metropolitan areas, which in 1963 gained control of the house for the first time in the state's history. Legislative reapportionment on the basis of population was approved in 1966. The county unit rule applied to primary elections since 1910 was declared unconstitutional by a federal court in 1963. From 1948 the legislature met annually, with a 90-day session in even years. The short session is limited to budgetary matters and emergency legislation for the general public welfare.

In 1922 the administrative branch of the state government was completely reorganized. A merit system was established and by the mid-20th century more than 70% of the state employees were in the classified service. The Maryland state planning commission was established in 1933 to prepare a long-range capital improvements program as well as to recommend a program of needed improvements each year. A legislative council was created in 1939 to give continuous study to the state government and to sponsor a legislative program for each session of the assembly. Other notable advances include the creation of the department of public improvements to lend technical advice and assistance to the board of public works.

Justice is administered by the court of appeals (supreme court), four appellate circuits, intermediate circuit courts in the counties and the city of Baltimore, orphans' courts, trial magistrates' courts and peoples' courts. The state is divided into eight judicial circuits, one comprising the city of Baltimore and the other seven comprising two or more counties. In each circuit there is a chief judge and a varying number of associate judges, all elected for 15-year terms. Under the reorganization act of 1943, the court of appeals consists of five judges, one elected from each of three appellate circuits and two from the fourth appellate circuit (Balti-

VIEWS OF MARYLAND

Top left: Oyster dredges at anchor in Cambridge, southeastern Maryland. State law permits dredging only from sailboats

Centre left: Drying tobacco in southern Maryland, on the western shore of Chesapeake bay. Five counties on the western shore grow about

30,000,000 lb. of tobacco a year

Top right: View of rich dairy and wheat farmland in Frederick county, along the Piedmont plateau in the western section of the state

Bottom: Duck hunting on the eastern shore of Chesapeake bay

more) for 15 years. The chief judge of the court of appeals is the administrative head of the state's judicial system. Judges of the court of appeals have no original jurisdiction.

In 1916, by constitutional amendment, Maryland became one of the first states to adopt the executive budget. Under this system the governor submits the budget to the legislature in the form of a budget bill. The legislature can reduce or eliminate appropriations for executive and administrative purposes, increase but not decrease judicial appropriations and either increase or decrease legislative appropriations. The budget bill becomes law as soon as passed by the legislature.

A separate agency, the department of budget and procurement, was established in 1939 to assist the governor in preparing the budget. The form of the budget remained unchanged until 1951 when the recommendations of the commission on administrative organization of the state were submitted and then approved. During fiscal year 1953, the change was effected from the then line-item budget to a program or performance-type budget, which for the first time included in one comprehensive budget all funds—general, special, federal and capital collected and disbursed by the state. The first budget adopted under the new system was for fiscal year 1954. The comptroller's department administers most revenue of the state. Exceptions are the property tax, which is administered by the state tax commission through Baltimore city and the counties, and certain fees and licences.

Principal sources of income for the state in the 1960s were the state income tax, about 21%; federal funds, 21%; gasoline taxes and motor vehicles revenues, 20%; and the state sales and use tax, 15%. Expenditures in order of importance were for public education, about 30%; highways and nonhighway transportation, 27%; payments to civil divisions of the state, 12%; health, hospitals and mental hygiene, 10%; and public welfare and employment security, 8%.

POPULATION

Maryland's population, approximately 200 in 1634, increased to 8,000 by 1660, to 43,000 by 1710, to 319,728 by 1790, to 687,049 by 1860, to 1,295,346 by 1910, to 2,343,001 by 1950 and to 3,100,689 by 1960. The population per square mile by 1960 was 293.2 as compared with 49.6 for the United States as a whole. The urban population was 2,253,832 or 72.7%, while the rural population was 846,857, or 27.3%. All of the Baltimore standard metropolitan statistical area (Baltimore city and Anne Arundel, Baltimore, Carroll and Howard counties) and part of the Washington, D.C., area (Montgomery and Prince Georges counties) are in Maryland. The two areas comprise 78% of Maryland's population.

Maryland's population was distributed by colour and nativity in 1960 as follows: 80% native white; 3% foreign-born white; and 17% nonwhite, practically all Negro. There were 98 males per 100 females in the native white population and 97 in the non-white population; 7.3% of the population was 65 years of age or older; and 57.6% of the population 14 years old or over was in the labour force.

EDUCATION

Maryland's public-school system was established in 1865 and completely revised in 1916. It is headed by a state board of seven lay members appointed by the governor for seven years. Their principal functions are to formulate policy and provide leadership to local units. The state board appoints a state superintendent for a four-year term. He directs the department of education and administers the school system in general.

In 1947 a comprehensive program was launched for building schools, increasing salaries, raising standards and improving the curriculum. In 1951 complete transition to a 12-year system was effected. During the 1950s and 1960s about 900 new public-school classrooms were added each year. Local taxes and funds from the state school building incentive fund made this expansion possible. Maryland made rapid progress, particularly in Baltimore, in integrating white and Negro pupils in its public schools in accord with the supreme court decision of 1954.

The University of Maryland, dating from 1807, was enlarged in

1920 by the merger of the university, consisting of the schools of law, medicine, nursing, pharmacy and dentistry at Baltimore, with Maryland State college (formerly known as Maryland Agricultural college) at College Park. The Negro branch, Maryland State college, at Princess Anne, was also included.

The university made rapid strides after World War II, increasing from 10,104 students in 1951 to nearly 15,000 by 1960. There was an additional increase in off-campus enrollment, including overseas branches, from 16,737 to nearly 34,000. Capital improvements and many valuable services were pushing the university toward top rank among the nation's land-grant institutions.

Johns Hopkins university in Baltimore, often described as the first true university in America, was established from a fund of nearly \$7,000,000 bequeathed by Johns Hopkins, a wealthy Baltimore merchant, in 1873 for the founding of a university and hospital. A leading educational institution, it comprises the hospital, the school of medicine, the school of hygiene and public health, the faculty of philosophy (conferring A.B., M.A., and Ph.D. degrees), school of engineering, school of business and industrial management, McCoy college, the school of advanced international studies and other units.

Other institutions of higher learning in Maryland are: Washington college (nonsectarian), Chestertown (dating to 1707 as a secondary school and chartered in 1782 as a college); St. John's college (nonsectarian), Annapolis (established as King William's school in 1696 and chartered as a college in 1784); Western Maryland college (Methodist) in Westminster (established in 1868); Mount St. Mary's (Catholic, 1808) and St. Joseph's college (Catholic, 1809), both in Emmitsburg; and in Baltimore, St. Mary's seminary and university (Catholic, 1791), Loyola college (Catholic, 1852), College of Notre Dame of Maryland (Catholic, 1873), Mount St. Agnes (Catholic, 1890), Goucher college (nonsectarian, 1885), Morgan State college (founded in 1867 as a private Negro college, taken over by the state in 1939); Hood college in Frederick (United Church of Christ, 1893); Woodstock college at Woodstock (Catholic, 1867).

State teachers' colleges are located at Towson, Salisbury, Frostburg, Bowie and Baltimore (Coppin state). Junior colleges are at Baltimore, Takoma Park, Hagerstown, Frederick, Bel Air, Catonsville and Essex. Other institutions include the University of Baltimore and miscellaneous business and professional colleges.

Other outstanding institutions of an educational and cultural nature are Peabody Conservatory of Music (1868), Maryland Institute for the Promotion of Fine and Mechanic Arts (1825) and the Enoch Pratt free library (with numerous branches), established in 1866.

PUBLIC HEALTH AND WELFARE

The state department of health, governed by the state board of health and mental hygiene, administers Maryland's public health program. Each county also has its health board and health officer. The county is the functional unit. Some municipalities in the counties also make financial contributions to the health program.

The department operates four tuberculosis hospitals (the Victor F. Cullen, Henryton, Mount Wilson and Pine Bluff state hospitals) and three chronic disease hospitals (Montebello, Deer's Head and Western Maryland state hospitals). The department of mental hygiene controls mental hospitals at Cambridge, Sykesville, Catonsville, Crownsville and Owings Mills. In 1955 the Patuxent Institution for Defective Delinquents was opened. Two other institutions were authorized in the late 1950s: the Institution for Criminally Insane at Jessups and the Long Term Care colony near Pikesville.

The state department of public welfare co-ordinates and directs all welfare activity in the state. It supervises and controls the county welfare boards; investigates public and private institutions, organizations and agencies of a charitable nature; administers the child labour laws; and licenses agencies and institutions having care and custody of minors. It controls the state's four training schools—Boys' Village, Maryland Training school, Barrett school and Montrose school. Other state agencies in welfare activities are the state industrial accident commission, the department of

employment security and those supervising the state penitentiary and other penal institutions.

THE ECONOMY

Occupations and Employment.—The total labour force in Maryland exceeds 1,200,000, about 3% of whom are agricultural workers. Nonagricultural employment is as follows: manufacturing employs about 25%; trade about 18%; public administration about 11%; service industries about 8%; and all others, 38%. Total personal income in Maryland rose steadily during the 1950s and exceeded \$7,000,000,000 in the 1960s. Thousands of men and women in Maryland, particularly in the rapidly growing suburbs of Washington, D.C., such as Bethesda-Chevy Chase, Silver Spring and Takoma Park, are employed by the federal government in a great variety of occupations.

Agriculture.—Although its small size and the diversity of its farm crops prevent Maryland from becoming an important factor in the national agricultural picture, the state nevertheless has a thriving farm population. The state has a variety of good soils and a climate adaptable to a wide range of production. There are also excellent transportation facilities, readily accessible markets and fine agricultural services of the University of Maryland.

Tobacco production predominates in southern Maryland. Hay, grain, livestock and dairy production typify the central counties, while the eastern shore excels in poultry raising and truck farming. In the state as a whole, the 1950s saw a marked decline in the production of corn, Irish potatoes, horses and sheep, but the decade brought a steady increase in the production of milk, eggs and chickens. Maryland ranks high nationally in commercial broiler production, and in its output of tomatoes and strawberries. The state produced approximately 400,000,000 eggs annually in the 1960s.

Of the 6,323,840 ac. of land area in Maryland, about 60% is in farms. The harvested acreage totals about 1,500,000. The number of farms declined from about 42,000 before World War II to fewer than 32,000 in the second half of the 20th century. The number of acres in farms declined for the same period from about 4,000,000 to about 3,500,000. Meanwhile, the average size of farms increased from approximately 100 to 120 ac., while the average farm increased in value from about \$6,500 to more than \$20,000. The value per acre jumped from \$65 to \$177. Principal crops are corn, wheat, oats, barley, rye and hay. Crops rank first in terms of income, followed by livestock and livestock products, dairy products and commercial broilers.

Manufacturing.—Maryland's leading source of wealth, manufacturing, steadily increased in importance during and after World War II. Although centred mainly in Baltimore, substantial industrial gains were made in Cumberland, Hagerstown, Frederick, the central counties generally, and Salisbury and Cambridge on the eastern shore. Extensive vegetable, poultry and fish processing developed on the eastern shore. The number of industrial establishments in Maryland increased rapidly during the 1950s and 1960s. In terms of number of employees, Maryland's major industry groups were primary metals, food and kindred products, transportation equipment, chemicals, machinery, apparel and related products, lumber and wood products, furniture and fixtures, paper products, printing and publishing, and some mining.

Fisheries.—Maryland is known everywhere for its seafood and has developed a substantial fishing industry. The commercial fish catch from the Atlantic ocean and the Chesapeake bay and its tributaries exceeds 17,000,000 lb. annually. The leading types of fish are striped bass, roe shad, menhaden and river herring. The commercial catch of shellfish exceeds 42,000,000 lb. annually. The most valuable catch is that of oysters, which totals approximately 2,250,000 bu. The oyster industry, after a marked decline due to lack of proper conservation measures, has made a comeback as a result of shell planting or seeding and other measures. Approximately 280,000 bu. of seed oysters were made available to private planters by the state during the 1950s, and 1,400 additional acres of barren bottom were leased to private planters. The annual hard crab catch exceeds 20,000,000 lb. The new soft-shell clam industry made rapid progress after World War II.

Trade and Finance.—With a constantly expanding economy, Maryland developed a large retail and wholesale trade. By 1960 it had approximately 25,000 retail establishments with an annual sales volume of about \$3,500,000,000. More than half of this total was accounted for in the Baltimore metropolitan area. Wholesale trade was conducted by about 3,000 establishments.

During the 1960s Maryland had about 150 active banks (including national, state, commercial, savings and private banks). The state also had many chartered credit unions and industrial finance companies.

Transportation and Communication.—Maryland was a pioneer in road building in the early 20th century, but fell behind other states during the 1930s and was compelled to begin a great road- and bridge-building program at the end of World War II. The Chesapeake bay bridge was built between 1949 and 1952 at a cost of \$45,000,000, financed by a bond issue. The Washington-Annapolis freeway was opened and a new Severn river bridge filled the last gap in a direct link between the Chesapeake bay bridge and the freeway. The Baltimore-Washington expressway was opened in its entirety early in 1954. Dual highways were built between the Delaware line and Washington, between Washington and Frederick, and between Baltimore and Frederick. In 1957 an under-harbour tunnel from Fairfield to Canton, costing \$130,000,000 including approach roads, further facilitated traffic through Baltimore. By the 1960s there were more than 1,000,000 motor vehicle registrations in the state and more than 20,000 mi. of roads and highways nearly all of them surfaced. There were no toll roads in Maryland, but tolls were paid to use the Chesapeake bay bridge, the Baltimore harbour tunnel, the Susquehanna river bridge at Havre de Grace and the Potomac river bridge in southern Maryland.

The state is traversed by three main railroads. Altogether, railroads operate about 1,500 main-line track miles within the state. Bus lines serve all parts of the state and major airlines serve Baltimore and other parts of the state.

The state's first radio station began to operate in 1922 and its first television station in 1947, both in Baltimore.

Maryland has about 70 weekly newspapers, the oldest being the *Maryland Gazette-Glenburnie News* (Annapolis, 1727), first published as the *Maryland Gazette*. The *Baltimore Sun* is the oldest daily newspaper.

MARY MAGDALENE, SAINT, a disciple of Jesus mentioned in all four canonical Gospels as one of the first witnesses to the empty tomb (Mark xvi, 1; Luke xxiv, 10) or to the risen Lord (Matt xxviii, 9; John xx, 1; Mark xvi, 9). In Luke viii, 2 and Mark xvi, 9 she is described as having had seven demons expelled

from her; for this reason the anti-Christian writer Celsus attacked her as an "insane" witness to the resurrection (for some reason she is not included in the "official" list of witnesses in I Cor. xv, 5-7). Gnostics, on the other hand, regarded her as a favourite disciple of Jesus and a medium of secret revelation (she is so described in the Gnostic works Gospel of Mary, Gospel of Philip and Pistis Sophia). Origen and other early exegetes usually viewed her as distinct from the woman or women who anointed Jesus' head or feet (named Mary in John xii, 3; cf. Mark xiv, 3; Matt. xxvi, 6-7; Luke vii, 36-38), but this identification gradually gained ground and was emphatically set forth by Gregory the Great. After his time the cult of St. Mary Magdalene flourished in the west (feast day July 22). In late legend she accompanied St. John to Ephesus, where she died and was buried. The primary theme related to her cult was that of the repentant sinner (Luke vii, 44-50) witnessing the risen Christ.

See U. Holzmeister in *Zeitschrift für katholische Theologie*, 46:402 ff., 556ff. (1922); V. Saxer, *Le culte de Marie Madeleine en occident* (1959).

MARYSVILLE, a city of northern California, U.S., is located in the centre of the Sacramento Valley, 42 mi. N of Sacramento, at the confluence of the Yuba and Feather rivers. Settled about 1842, it was an important wholesale and retail centre for the northern gold mines. After 1884, however, mining was gradually replaced by farming as the mainstay of the economy. For comparative population figures see table in CALIFORNIA: Population.

MASACCIO (TOMMASO DI GIOVANNI DI SIMONE GUIDI) (1401-1428), the first and greatest Florentine Renaissance painter, was born at San Giovanni Valdarno, near Florence, on Dec. 21, 1401. His father, a notary ser, Giovanni di Monte Vassai, died in 1406. In 1422, Masaccio was enrolled in the Arte dei Medici e

Speziali in Florence, and in 1424 became a member of the Compagnia di S. Luca. According to Giorgio Vasari, he owed his early training as a painter to Masolino da Panicale (q.v.) and this is probable, since Masolino came from the same region and Masaccio's earliest surviving work was painted in collaboration with the older artist. This is the "Virgin and Child with St. Anne," painted about 1420 and now in the Uffizi gallery, Florence, to which Masaccio contributed the uppermost angel on the right, the foreshortened left hand of St. Anne, and the seated Virgin and Child. The marked contrast between the contributions of the two artists, one soft and lyrical, the other recessive and sculptural, continues

throughout their whole collaborative careers. About 1424 they again worked side by side on a double-sided altarpiece, commissioned from Masolino for Sta. Maria Maggiore in Rome, to which Masaccio contributed at least one lateral panel with SS. Jerome and John the Baptist, now in the National gallery, London.

In Dec. 1426, Masaccio completed an altarpiece for the church of the Carmine at Pisa, of which a central panel, of the Virgin and Child enthroned, is in the National gallery, London; a central pinnacle of the Crucifixion is in the Museo di Capodimonte at Naples; two panels of saints in half-length are in the Lanckoronski collection, Vienna, and the Kaiser Friedrich museum, Berlin; and four pilaster panels and three predella panels are also in the latter gallery. By this time, Masaccio, despite his youth, was a mature artist, and the altarpiece is the first panel painting in which a Renaissance style is fully employed. Among the many novel features of this revolutionary painting may be noted the accomplished use of linear perspective in the central panel, the Brunelleschian architecture of the throne, and the illusionistic modeling of the figures, in which the forms are suffused in light. At the same time,

the work far transcends what is normally understood by the term naturalism, and the panel in Naples is one of the most moving representations of the Crucifixion in Italian painting. A fresco of the Trinity, commissioned for Sta. Maria Novella in Florence, probably in 1427, shows a barrel-vaulted hall, closed on its outer face by columns and pilasters, with a representation of the crucified Christ supported at the back by a standing figure of God the Father and accompanied by the Virgin and St. John; the two donors kneel to right and left outside the scene. The spatial scheme is the first example of the application of linear perspective to the art of fresco painting. The fresco is without precedent also in its iconography, which recalls certain works executed by the sculptor Donatello.

Masaccio's most important work is the decoration of the Brancacci chapel in the Carmine church in Florence, for which he executed what are possibly the greatest Italian frescoes and certainly the greatest frescoes of the 15th century. There are no documents relating to Masaccio's activity in the Brancacci chapel, and a number of widely differing hypotheses respecting it have been advanced. It seems probable that this decoration (which consisted of scenes from the life of St. Peter) was first entrusted to Masolino, who about 1425 executed the frescoes in the upper register (destroyed). After an interval, work was resumed in the summer of 1427 jointly by Masaccio and Masolino. Masaccio is generally agreed to have been responsible for the frescoes of the "Expulsion from Paradise," the "St. Peter and the Tribute Money," and "St. Peter Enthroned" (unfinished) on the left wall, and for the "Baptism of the Neophytes," the "Distribution of the Goods of the Community" and "SS. Peter and John Healing the Sick With Their Shadows" on the altar wall. The contrast between the styles of Masaccio and Masolino appears most forcibly in the magnificently virile "Expulsion From Paradise" of Masaccio and the fresco of "Adam and Eve" by Masolino on the wall opposite. The most impressive of these astonishing frescoes is the "Tribute Money," where the figures, with their heavy drapery, are set against a background of seemingly limitless depth in a foreground area defined by a receding building on the right. In this and in the other frescoes the effect of overwhelming grandeur is partly induced by the rapt absorption of the participants in the event that is portrayed. The portrayal of the sick men in "SS. Peter and John Healing the Sick With Their Shadows" and of the dead Ananias in the "Distribution of the Goods of the Community" forms one of the most momentous advances in representation in western art.

In about 1428, Masolino began work on the decoration of the Branda chapel in S. Clemente in Rome. The frescoes in this chapel were ascribed by Vasari to Masaccio, and it is possible that he accompanied Masolino to Rome, where he died, at the age of 27, in the autumn of 1428. Since his death the supreme importance of Masaccio's contribution to the development of painting has never been in doubt, and his frescoes in the Carmine have been copied by Michelangelo and countless other artists. Though all of his known works were produced in a period of eight years, he occupies in his own art a position analogous to those of Brunelleschi in architecture and Donatello in sculpture.

(J. W. P.-H.)

MASADA, a natural hill fortress in the eastern Judean Desert, on the Dead Sea coast in Israel, where the Jews made their last stand against the Romans in the Jewish revolt of A.D. 66-73. The hill is situated about 32 mi. (51 km.) S of Khirbet Qumran, where most of the Dead Sea Scrolls were found. The boat-shaped fortress covers 20 ac. (8 ha.).

Probably first used as a fortress by Alexander Jannaeus, Hasmonaean ruler of Judaea (103-76 B.C.), Masada also served as a stronghold in the contest between the Hasmonaean and Herod the Great. Herod completely rebuilt the fortress (c. 35 B.C.). After the exile of his son Archelaus (A.D. 6) a Roman garrison was established at Masada. It was massacred by Jewish Zealots in A.D. 66, and by A.D. 72 Masada was the last Jewish stronghold resisting the Romans. The Roman tenth legion, with auxiliaries,

besieged the fortress during A.D. 72–73 and, using siege machines, broke into the fortress from the west. The defenders (numbering 960, with women and children), led by Eleazar ben Jair (Yair), preferred to die as free men and took their own lives, after having burned their possessions. In the 5th and 6th centuries monks built a church and cells there.

Herod's buildings on the summit of Masada were excavated mainly in 1963 and after under the auspices of the Hebrew University, the Israel Exploration Society, and the Department of Antiquities of the State of Israel, under the direction of Yigael Yadin. The main features revealed by the excavations were a strong casemated wall encircling the flat mountain top; Herod's villa ("the hanging palace"); a well-appointed bathhouse; an administrative palace; and storehouses, some with remnants of their original contents. Huge cisterns supplied water collected, by means of aqueducts, from the flood waters that swept past nearby.

The Jewish Zealots who massacred the Roman garrison in A.D. 66 settled mainly in the casemates. They built a synagogue and ritual baths as well as household installations. The extreme dryness helped to preserve their possessions and, above all, scroll and papyrus fragments. The scroll fragments discovered include parts of Genesis, Leviticus, Deuteronomy, Ezekiel, Psalms, Ecclesiasticus, and a sectarian scroll of the Qumran type, "The Song of the Heavenly Sabbath Sacrifices." These finds predate the year A.D. 73 and thereby render probable the early date of the similar finds at Qumran (see DEAD SEA SCROLLS). Eight camps built by the tenth legion at the foot of the hill in A.D. 72 are well preserved.

See Y. Yadin, *Masada: Herod's Fortress and the Zealots' Last Stand* (1966).

MASAI is a name commonly but erroneously used to identify a single tribe in east Africa. However, it is essentially a linguistic term referring to several tribes that together numbered about 225,000 in the 1960s and speak Maa, a Nilo-Hamitic language. Only the Pastoral Masai, who number about 115,000 and range along the Great Rift valley of Kenya and Tanganyika, are called IlMaasai by Maa-speaking peoples. The others use their tribal names, including the Samburu (22,000) of Kenya and the semi-pastoral Arusha (68,000) and Baraguyu or Kwavi (20,000) of Tanganyika. Failure to distinguish among these groups, with their different origins and modes of life, has tended to impede their accurate description. The Arusha, for example, do some mixed farming, practise ancestor worship and have a segmentary lineage system—traits absent among the Pastoral Masai.

The Pastoral Masai are the largest and perhaps best known of the Maa-speaking tribes. They are tall and slender with good features and well-defined noses. The heads of women, and of married and uninitiated men, are shaved. Young unmarried men, who are organized into warrior groups, wear their hair plaited into queues hanging down the back and over the forehead. Males wear very little clothing, but women are scrupulously clothed from childhood on with dressed skins or, increasingly today, red-ochred cotton cloth. Beads, metal armlets and leg bands, necklaces and bracelets are popular with both sexes.

The Pastoral Masai are proud seminomads who try to subsist entirely on the milk, meat and blood of their livestock. Cattle of the humped zebu type are the mainstay, though sheep, goats and pack donkeys also are kept. The Pastoral Masai neither hunt nor grow crops. Although most are permitted to eat grains and vegetables in periods of want, warriors may not. An intoxicating honey beer is drunk by men and women, and most adults except the warriors chew tobacco or use snuff. Their principal weapons are long-bladed spears, wooden knobkerries and short swords. Smelting and ironwork are held ritually unclean and metal objects are imported.

The basic residence unit for the Pastoral Masai is the kraal camp, consisting of a large circular thornbush fence within which mud-dung igloo-like houses are built on the perimeter by women. Each head of a polygynous family has his own gate to the camp, and his wives build separate houses to the right or left of the gate in order of seniority. Livestock, branded on the ear according to the owner's clan, are taken into the camp at night as pro-

tection against predatory animals. Cattle are herded and watered by boys and men but milked mainly by women and girls. Warriors may not yet marry and, during their period of military service, live in separate villages (*manyata*) where they are visited by unmarried girls.

Socially, the Pastoral Masai form a number of patrilineal exogamous clans grouped into moieties. A most distinctive feature is their highly formalized age set (*q.v.*) system consisting of groups of coevals who were initiated (circumcised) into adult life during the same open-initiation period. These hierarchical age sets not only delimit groups authorized to make decisions for the tribe but also provide groups to act on the decisions. The centre of political authority lies with the set of elders separated by one intervening age set from the existing senior warriors, over whom they have special right of command; judicial and legislative functions reside in a council of elders headed by this age set. Traditionally there were no chiefs; however, in 1958 Pastoral Masai of Tanganyika elected one of their young educated men as a sort of paramount chief of the Tanganyika Masai Federal council.

Ceremonial events are directed by a ritual expert (*oloiboni*) who, although he has no political power, is religious head of his tribe. Masai traditionally hold that earth and sky were once one; only after their separation did God (Ngai) leave men to reside in the sky, from which he let down cattle for Pastoral Masai as a divine gift. As a result of this separation the earth and things associated with it are regarded as unpropitious and Masai are reluctant to dig in the soil, plant seed or bury their dead, which even today are left out to be eaten by hyenas.

Today the Pastoral Masai are perhaps most remarkable for their resistance to cultural changes occurring around them, as in their attempt to subsist entirely on livestock. In the 1960s fewer than 1,000 of their young men and women had the equivalent of a secondary (high school) education; their elders adhere strongly to traditional ways. See also references under "Masai" in the Index. **BIBLIOGRAPHY.**—H. Fosbrooke, "An Administrative Survey of the Masai Social System," *Tanganyika Notes and Records*, vol. 26 (1948); T. O. Beidelman, "The Baraguyu," *ibid.*, vol. 55 (1960); P. H. Gulliver, *Social Control in an African Society—a Study of the Arusha Agricultural Masai of Tanganyika* (1963). (AL. H. J.)

MASANIELLO (properly TOMMASO ANIELLO) (1620–1647), a fisherman who became the nominal head of the popular insurrection of July 1647 in Naples, was born in Amalfi in June 1620. Under Spanish rule the government of Naples had long been controlled by the nobility, and the common people were exasperated when a tax on fruit was announced (Dec. 1646) to raise money for the biennial tribute to Spain. Giulio Genoino, a former *eletto* or nominated spokesman of the people, planned demonstrations to persuade the Spanish viceroy, Rodrigo Ponce de León, duque de Arcos, to remit the tax and chose Masaniello to lead a band of urchins in starting them. A riot that began on July 7, 1647, grew into an insurrection against noble rule, but expressly not against Spain. The people demanded the democratic "privileges" granted by the Holy Roman emperor Charles V (Charles I of Spain) and by the withdrawal of all imposts. Prisons and armouries were attacked, excise booths and noble houses were fired and the viceroy, having revoked the tax on fruit, took refuge in the Castelnuovo fortress. The insurgents proceeded to the summary execution of unpopular persons. A settlement negotiated between the insurgent leaders and the cardinal archbishop of Naples, Ascanio Filomarino, was approved by the viceroy on July 10 and submitted to the people in the Carmel church. Though an attempt was then made on Masaniello's life, the settlement was ratified next day, and Masaniello, dressed in cloth of gold, was recognized as captain general of the people by the viceroy. More nobles were put to death. On July 13, however, when an oath was sworn in the cathedral between the viceroy and the people, Masaniello was drunk; and on July 15, raving madly for more slaughter, he was taken into custody by Genoino. On July 16, having escaped to the Carmel church, he was shot outside the monks' dormitory by assassins hired by the nobles. The people mutilated his body, and the viceroy rewarded the assassins; but on July 17 a new riot drove the viceroy back to the Castelnuovo and the people gave Masaniello a solemn funeral.

Masaniello's life was made the subject of an opera, *La Muette de Portici* (1828), by Daniel Auber and Eugène Scribe.

See M. Schipa, *Masaniello* (1925).

MASARYK, JAN GARRIGUE (1886–1948), Czechoslovak statesman, the son of T. G. Masaryk, was born in Prague on Sept. 14, 1886. He went to the United States in 1907 and undertook a variety of jobs; he returned to Prague before the outbreak of World War I. During the war he served in a Hungarian regiment, mostly in Poland. When Czechoslovakia became independent he went into the foreign office; in 1919 he was sent as *chargé d'affaires* to Washington, but was soon transferred to London, where he became counselor of legation. In 1921 he returned to Prague to become secretary to the foreign minister, Edvard Benes.

In 1925 Masaryk was appointed Czechoslovak minister in London; he resigned after the Munich agreement of Sept. 30, 1938. In World War II, when the Czechoslovak government was provisionally reconstituted in London in July 1940 (after the fall of France), he became its foreign minister. His broadcasts to occupied Czechoslovakia from London throughout the war made him for the first time a popular figure in his own country, from which he had been so long absent. In the spring of 1945 he accompanied President Benes to Moscow, then went to San Francisco for the inauguration of the United Nations, returning to Prague in July. Although he found relations with Moscow increasingly difficult, especially after the Soviet veto on the acceptance of aid through the Marshall plan, he remained foreign minister until his death. He was one of the three non-Communist ministers to whom bombs were sent by post on Sept. 11, 1947. After the Communist *coup d'état* of Feb. 25, 1948, he remained at his post at Benes' request. His body was found on March 10; it appeared that he had thrown himself out of the window of his room at the foreign office. His wartime broadcasts were published under the title *Speaking to My Country* (1944).

See Sir R. H. Bruce Lockhart, *Jan Masaryk* (1951); Robert Powell (J. Emlyn Williams), "Jan Masaryk," *Slavonic and East European Review* (April 1950). (E. W.)

MASARYK, TOMAS GARRIGUE (1850–1937), philosopher, Czechoslovak patriot and first president of Czechoslovakia, was born on March 7, 1850, near the town of Hodonin in Moravia, on the frontier with Hungarian Slovakia. His father was a coachman employed on one of the Austrian imperial estates, a native of Kopčany in Slovakia; his mother came from a half-Germanized Czech family in Hustopece, in Moravia. As a child Masaryk spoke Czech and a smattering of German; he began his education at a Czech school at Cejkovice. Then his parents sent him for two years to a German *Realschule* in Hustopece, intending that he should become a teacher; but when he was 14 this idea was dropped, and the young Masaryk became a locksmith's apprentice in Vienna, then a blacksmith at Cejc. A year later, however, in 1865, a former schoolmaster of his persuaded his parents to return to the original plan of a teaching career. Accordingly Masaryk entered the German grammar school in Brno and began to study there. In Brno he earned money by tutoring in the family of a director of the police.

It was at this time that Masaryk developed a rebellious disposition, taking exception to some of the dogmas of the Roman Catholic Church and refusing to go to confession. As a result he was obliged to leave the grammar school. Yet he was able to continue his studies in Vienna with distinction, obtaining his doctorate in philosophy from the university in 1876. He then studied for a year in Leipzig where he met an American student of music from New York, Charlotte Garrigue, whom he married in 1878.

In 1879 Masaryk returned to the University of Vienna as a lecturer in philosophy; he was already well known as a Platonist. In 1881 he published in German his first important sociological work, *Der Selbstmord als soziale Massenerscheinung der modernen Zivilisation* ("Suicide as a Mass Phenomenon of Modern Civilization"). In 1882, when the University of Prague was divided into separate Czech and German institutions, Masaryk was appointed to one of the Czech professorships. In 1885 he published an important work, *Zakladove konkretni logiky* ("The Bases of Concrete Logic"; Ger. trans. 1887).

In 1883 Masaryk had founded a critical monthly review, *Athenaeum*. It was here that the famous manuscripts of Kralovy Dvur and Zelená Hora (Königinhof and Grünberg), produced in the early 19th century by two overzealous Czech patriots in order to provide proof of the literary achievements of medieval Bohemia, were exposed as forgeries. The authenticity of the manuscripts had already been questioned by Slavonic philologists, but it was only in 1886 that they were conclusively proved to be forgeries after a philological analysis by the great Czech expert, Jan Gebauer, and an examination in sociological terms by Masaryk himself. Another monthly review, *Naše Doba* ("Our Epoch"), was founded by Masaryk in 1893.

During the last two decades of the 19th century Masaryk's activities were tireless and varied. He was an instructor in the Sokol Czech nationalist gymnastic association. He lectured to the clubs and societies of Prague on unconventional subjects and published unpopular books. He was an advocate of the eight-hour day and of education for women. His sociological work led him to a study of Marxism: in *Otazka socialismu* ("The Social Question," in Czech and German, 1898) he criticized historical materialism.

Meanwhile, in 1889, Masaryk had transformed a review called *Čas* ("Time") into a political weekly. This was the beginning of his political career. At this time the Old Czech party, led by Vladislav Rieger, was losing ground to the more intransigent nationalist Young Czechs, who invited Masaryk to campaign with them in the elections to the Vienna *Reichsrat* in 1891. The Young Czechs won handsomely over the Old Czechs and Masaryk became, together with Karel Kramář, one of their deputies in Vienna. This was perhaps the only obvious political mistake that he ever made, and he resigned his seat in 1893 in order to escape from emotional nationalism in favour of his gospel of what he called "realism." For him the national cause was linked with the tradition of moral integrity of the Bohemian Brethren. For this reason he had struggled to dissociate the national cause from the forgeries and now set about, through the Realist party which he founded, to identify it with a scientific, humane and liberal approach to all the questions of the day. This was a period of rising anti-Semitism in Austria, and it was characteristic of Masaryk that in 1899 he condemned the trial of the half-witted Jewish youth Leopold Hilsner on a charge of ritual murder. His moral courage gave him a great name with the younger generation, not only of Czechs and Slovaks but also of Croats and Serbs, for whom Prague became a favourite meeting place.

In 1900 Masaryk's followers founded what they called the Progressive party, though they continued popularly to be known as Realists. Elections to the *Reichsrat* were held in 1907 immediately after the franchise had been made general for men over 24, and Masaryk was elected with a notable following. In 1908 he attacked the formal annexation of Bosnia-Herzegovina by Austria-Hungary. He later played a great part in relation to the Zagreb treason trial of 53 Serbs of Croatia-Slavonia and to the libel action against the pro-Austrian writer Heinrich Friedjung which ensued: thanks to his own investigations he was able to show that the case for the prosecution in the Zagreb trial rested on documents forged at the Austro-Hungarian legation in Belgrade. His disclosures in the *Reichsrat* (1909) and in the Austro-Hungarian delegations (1910) caused the proceedings in the Zagreb trial to be quashed and obliged Friedjung to retract his accusations against the Serbs. Inevitably Masaryk incurred the intense displeasure of official circles in Vienna, but among the Slavs and in the world at large his reputation was enhanced. In 1911 he was re-elected to the *Reichsrat*.

It was as characteristic of Masaryk to expose the forgeries of Austrian diplomacy as of Czech romantics, and it should be emphasized that before 1914 he never thought of the Czechs and Slovaks as anything other than a nation within Austria-Hungary. With the outbreak of World War I the outlook seemed to him transformed. Having left Austria in Dec. 1914, he launched a campaign of propaganda in favour of Czechoslovak liberation from the Habsburg monarchy, which he now condemned as an oppressive and outmoded relic of the past. It was in Zürich, Switz., at the commemoration of the quincentenary of the burning of John Huss,

on July 4, 1915, that Masaryk first openly declared against Austria: he was supported on this occasion by the great French historian of the Czechs, Ernest Denis. (See CZECHOSLOVAKIA.) Finding his work in Switzerland hampered by enemy spies, Masaryk settled in London, where, at the invitation of Ronald Burrows, the principal, he joined the staff of King's college in Sept. 1915 and inaugurated the school of Slavonic studies in the University of London. In Nov. 1915 he formed a Czechoslovak Foreign committee which in Jan. 1916 was transformed into the National Czechoslovak council. Meanwhile, with the help of Wickham Steed and R. W. Seton-Watson, he worked to combat German and Magyar propaganda and to make western opinion familiar with Czechoslovak aspirations.

The Russian Revolution of 1917 enabled Masaryk to go to Russia. Several thousand Czech soldiers had gone over to the Russians and wanted to organize themselves into active military units. After some difficulty Masaryk induced the revolutionary Russian government to agree to the formation and equipment of an independent Czechoslovak army.

Masaryk went to the United States in May 1918. The result was Secretary of State Robert Lansing's declaration (May 29, 1918) of sympathy with the cause of Czechoslovak and Yugoslav independence. The Allied governments associated themselves with that declaration on June 3, 1918. The ice being thus broken, the Allied powers and the U.S. recognized the National council as the leading body of the Czechoslovak movement and also of the army that was fighting on the Allied side.

On Nov. 14, 1918, Masaryk was elected first president of the Czechoslovak republic. He was re-elected in May 1920, in May 1927, and again in May 1934, but in Dec. 1935 he resigned. Having seen his beloved pupil, Edvard Benes, elected to succeed him, he died at Lány on Sept. 14, 1937, mourned by the nation. His wife had died in 1923.

Masaryk ranks equally high as a philosopher and as a statesman. His "realism" was a reaction against the Teutonic idealism which developed moral speculation without reference to the practical affairs of life and against the Tolstoian philosophy of nonresistance to evil. Masaryk, as philosopher, stood for an integrated conception of life, in which the spiritual and religious took their place with the political aspects of the whole.

The following are the chief of Masaryk's many philosophical, sociological and political works (excluding those mentioned above): *Theorie Pravdepodobnosti a Humeova Skepse* ("The Theory of Probability and Hume's Scepticism"; 1882; Ger. trans., 1884); *Blaise Pascal* (1883); *Theorie defin vedle zasad T. H. Buckle* ("The Theory of History According to T. H. Buckle"; 1884); *Slavjanofilism I. S. Kirejevského* (1889); *Česka Otazka* ("The Czech Question"; 1895); *Karel Havlíček* (1896); *Zaklady marxismu filosofické a sociologické* ("The Philosophical and Sociological Foundation of Marxism"; 1898, also in German); *Jan Hus* (1899); *Rusko a Evropa* (1913; Eng. trans., *The Spirit of Russia*, 1919, reprinted with additions, 1955); *The Problem of Small Nations in the European Crisis* (1916); *The New Europe* (1918); *Světová Revoluce za valky a ve valce, 1914–1918* (1925; Eng. trans., *The Making of a State: Memories and Observations 1914–18*, 1927).

MASAYA, the smallest department in Nicaragua (land area 210 sq.mi.), located northwest of Lake Nicaragua, and the name of its capital city. The department is the most densely settled in the country; pop. (1963) 76,580. With fertile soils derived chiefly from volcanic ash and lava, Masaya is important agriculturally, producing especially tobacco, corn, beans and other vegetables, flowers and, on the slopes of Masaya volcano, coffee.

The city of Masaya, pop. (1959 est.) 29,449, on the shore of a crater lake of the same name, is famous for its flower gardens. It

is on the main line of the Pacific railway of Nicaragua; branch roads and railways connect the city with rich agricultural districts. It manufactures foodstuffs, leather, footwear, cigars, soaps, starch, rugs and hats.

(C. F. J.)
MASBATE, an island in the Philippine archipelago, centred 30 mi. S.W. of the southern tip of Luzon. Area 1,262 sq.mi. The island is adz-shaped, with mountain ranges along each axis, probably representing the intersection of the two main lines of Philippine faulting. Gold was mined for centuries near Aroroy in the north. Before World War II this area produced about 12% of the Philippine output; operations had ceased by the 1960s. The province of Masbate includes the much smaller Burias and Ticao islands. Total area 1,562 sq.mi. Pop. (1960) 335,971. The capital and principal trading town is Masbate (pop. [1960] 11,647), on the northeast; Cataingan, on the southeast, is also a trading centre. (R. E. HE.)

MASCAGNI, PIETRO (1863–1945). Italian operatic composer, one of the principal exponents of the realistic (*verismo*) style. Born at Leghorn on Dec. 7, 1863, he studied at the conservatory at Milan but, unable to submit to the discipline of his master, Amilcare Ponchielli, he left to join a traveling opera company. In 1889 he won the first prize in a competition with his one-act opera, *Cavalleria rusticana*, a setting of a Sicilian melodrama by Giovanni Verga. Produced at the Teatro Costanzi, Rome, on May 17, 1890, it was an instant success and subsequently maintained its popularity, usually being given with Leoncavallo's *I pagliacci* as a companion piece. *Le maschere* (1901), reviving the *commedia dell'arte*, is musically superior, though it had little success. He succeeded Arturo Toscanini as musical director of La Scala, Milan, in 1929. Among Mascagni's other operas are *L'amico Fritz* (1891), *Iris* (1898) and *Nerone* (1935), the latter glorifying Benito Mussolini. He died in Rome on Aug. 2, 1945. (Dv. H.)

MASCARA, chief town of an *arrondissement* in the *département* of Mostaganem, Algeria, 60 mi. S.E. of Oran. Pop. (1960) 44,839. It lies on the southern slope of Beni-Chougron and occupies two small hills separated by the Wad Toudman. The main European-built town is to the northeast and the Muslim town to the northwest. On the south the Eghriss plain is well cultivated (cereals, tobacco, vineyards, olive trees). The town is served by railway and is an important road junction. Mascara was long a typical north African garrison town, but it has become chiefly an administrative and commercial centre. Administrative buildings predominate; the town also has hospitals and clinics, as well as a theatre and stadium. The progressive disappearance of the ramparts has made possible the extension of the suburbs, with villas, gardens and apartment houses. The principal industry is the making of wine, the red and white wines of Mascara being held in high repute. There is also a considerable trade in grains and olive oil.

Mascara (i.e., "mother of soldiers") was the capital of a Turkish beylik during the Spanish occupation of Oran from the 16th to the close of the 18th century; but for most of that period it occupied a site about two miles distant from the present position. On the removal of the bey to Oran its importance rapidly declined. It was an insignificant place when in 1832 Abd-el-Kader (q.v.), who was born in the neighbourhood, chose it as the seat of his power. From one of its mosques he preached the Jihad. It was laid in ruins by the French in 1835, Abd-el-Kader retreating southward. He reoccupied Mascara in 1838, but lost it again in 1841. (AE. G.)

MASCARENE ISLANDS (occasionally MASCARENHAS), the collective title (derived from their discoverer, a Portuguese navigator named Pedro de Mascarenhas) of a group in the Indian ocean east of the Malagasy Republic (Madagascar), viz., Mauritius, Réunion and Rodrigues (qq.v.).

MASCARON, JULES (1634–1703), French Roman Catholic preacher, the son of a barrister at Aix-en-Provence, was born at Marseilles in 1634. He early entered the French Oratory and obtained a great reputation as a preacher. In 1666 he was asked to preach before the court, and he became a favourite with Louis XIV, who said that Mascaron's eloquence was one of the few things that never grew old. In 1671 he was appointed bishop of Tulle and in

1679 bishop of Agen. He continued, however, to preach regularly at court, being especially in request for funeral orations. A panegyric on Turenne, delivered in 1675, is considered his masterpiece. Mascaron died at Agen on Dec. 16, 1703.

Six of his most famous sermons were edited, with a biographical sketch of their author, by the Oratorian Borde in 1704.

See J. Lehanneur, *Mascaron d'après des documents inédits* (1878).

MASCART, ÉLEUTHÈRE ÉLIE NICOLAS (1837–1908), French physicist who applied photography to the mapping of spectra, was born on Feb. 20, 1837, near Valenciennes. He was educated at the École normale, obtaining his doctorate in 1864, and taught physics in lycées at Metz, Paris and Versailles. He became director of the central bureau of meteorology in 1871 and in 1872 succeeded Henri V. Regnault as professor of physics at the Collège de France. He also served as permanent secretary of the Academy of Sciences. Mascart died at Poissy on Aug. 26, 1908.

His early investigations were on optics; he constructed a quartz spectrograph and investigated a number of spectra farther into the ultraviolet. He also made determinations of standard wave lengths. His memoir on the effect of the proper motion of the earth on optical phenomena was awarded the Grand Prix des Sciences Mathématiques in 1874. Mascart made a number of determinations of electrical units and determined the electrochemical equivalent of silver. He was interested in the teaching of practical electricity and in its application to industry, and acted as adviser to the government in many matters. He wrote *Éléments de mécanique* (1866); *Traité d'électricité statique* (1876); *Traité d'optique*, 4 vols. (1889–93); *Leçons sur l'électricité et le magnétisme*, with J. J. Joubert (1882–86); and *Traité du magnétisme terrestre* (1900).

MASEFIELD, JOHN (1878–1967), English poet and novelist, who succeeded Robert Bridges as poet laureate in 1930, was born at Ledbury, Herefordshire, on June 1, 1878, and was educated at King's school, Warwick, and on the training ship H.M.S. "Conway." He was apprenticed aboard a windjammer, but when he was in New York he decided to abandon the sea and for several years earned a living in the United States. The activity of these early years was reflected in his work from the first, as in *Salt-Water Ballads* (1902); which contains the famous "Sea Fever." *Ballads* (1903) and *Ballads and Poems* (1910). His novels, *Captain Margaret* (1908), *Multitude and Solitude* (1909) and *Jim Davis* (1911), were excellent tales of action and spirit, but he found his best expression in narrative poetry and drama. "The Everlasting Mercy" made a literary sensation by its use of coarse language and detail when it appeared in the *English Review* in 1911; it was followed by *The Widow in the Bye Street* (1912), *Dauber and The Daffodil Fields* (both 1913), all sternly realistic narrative poems. Meantime Masefield had written two plays, *The Tragedy of Nan* (1909) and *Pompey the Great* (1910), the first allied in subject and setting to his long poems of village life, the second historical. *Lollington Downs and Other Poems* (1917) included a noteworthy sonnet sequence, and *Reynard the Fox* (1919) proved one of his most successful verse narratives. Here the country life that he knows so well is reflected faithfully and vividly, without the gloom of *Nan* and *The Everlasting Mercy*. The gradual awakening of the village on the morning of the meet, the gathering of the hunt, the stir and movement of horses and hounds, make up scenes that are perhaps his most sparkling. Later works include the novels *Sard Harker* (1924), *The Hawbucks* (1929) and *Badon Parchments* (1947); *A Macbeth Production* (1945); a book of verse, *On the Hill* (1949); and the autobiographical *So Long to Learn* (1952). He published some memorable war narratives in *Gallipoli* (1916) and *The Nine Days Wonder* (1941), about Dunkerque. He was awarded the Order of Merit in 1935. He died at his home in Berkshire on May 12, 1967.

(O. M. W. W.)

MASER, a device used for the amplification or generation of radio waves, usually in the microwave region. A device analogous to the maser, but which operates at optical frequencies, is called the laser (*q.v.*). The maser takes its name from an acronym coined by C. H. Townes from the descriptive phrase, "microwave amplification by stimulated emission of radiation." As the phrase implies, the operation of the device depends on radiant energy

emitted from a suitably activated material, the material being stimulated by incident energy at the same wave length.

A solid-state maser can be activated by storing energy supplied by a microwave source in a paramagnetic crystal (*see* PARAMAGNETISM). The stored energy is released from the crystal by the triggering action of an incoming resonant signal. Satisfactory performance ordinarily requires operation at low temperatures (-270° to -200° C.).

A gaseous maser can be activated by an electric field arranged to remove ground-level (unexcited) particles that would absorb incident energy from a molecular stream passing through it. (For an explanation of energy levels of atoms, *see* ATOM.) The remaining excited-level particles are then stimulated to emit energy as they pass through a resonant cavity. The power corresponding to the rate at which energy is emitted is greater than the power lost in the cavity, resulting in a net power gain (*see* ATOMIC AND MOLECULAR BEAMS).

The quantum-mechanical description of the properties of matter prescribes both discrete energy levels and the average number of particles occupying those levels. Normally, lower energy levels have a greater occupancy than do higher levels; therefore, matter absorbs a net amount of energy as a result of induced transitions from lower to higher levels (absorption) in excess of the amount of energy involved in transitions from higher to lower levels (emission). Maser activation produces greater occupation in the higher levels. Spontaneous emission, a source of random noise, also occurs, but the relative improbability of this at very short wave lengths accounts for the desirable low noise characteristic of maser amplifiers.

Because the energy-level spacing of certain gases is little affected by external forces, the gaseous maser produces power at a precisely maintained frequency corresponding to that spacing, a property that is useful for accurate measurement of time (*see* TIME MEASUREMENT). Since paramagnetic energy levels are more easily affected, solid-state masers have been more important as tunable preamplifiers for supersensitive microwave receivers used, for example, in radio telescopes.

See J. R. Singer, *Masers* (1959).

(J. W. M.)

MASERU, the capital town of Lesotho, Africa, is situated 4,950 ft. above sea level on the left bank of the Caledon river and near the territory's western border with the Orange Free State. Pop. (1966) 14,000. The annual rainfall is about 30 in. Only a few of the early mud-walled buildings remain, many having suffered in the "Gun War" of 1880. The residency, the home of the resident commissioner of Basutoland, incorporates the pre-1880 building but has been extensively enlarged. The octagonal National Council chamber, erected in 1910 when the council was first established, is the best-known architectural feature. There are several churches and schools including an African high school and a technical school which was opened in 1906, and a well-equipped hospital. The high court of Basutoland is housed in an imposing sandstone building. Maseru is linked to the South African railway system and by road to the various district headquarters, or "camps," in the western and northern lowland border country of Basutoland; it also has air services to administrative and trading centres in the mountainous interior.

The town is one of the oldest and most historic capitals in southern Africa, having been established in 1869 when the famous paramount chief of the Basuto, Moshesh, asked for the capital to be moved there from Mokema.

(Js. W.)

MASHAM, LADY ABIGAIL (d. 1734), favourite of Anne, queen of England, was the daughter of Francis Hill, a Levant merchant, who was ruined by speculation. He left four children for whom their cousin, Sarah Jennings, duchess of Marlborough, sought to provide. Through her influence Abigail entered the household of Queen Anne, and began, by compliant temper and Tory views, to supplant Sarah in the queen's affection. In June 1707 Marlborough suspected her of using her influence with the queen to further the political ends of her cousin, Robert Harley (*see* OXFORD, ROBERT HARLEY, 1st Earl of). Already Abigail had been married secretly in the queen's presence to Samuel Masham, a groom of the bedchamber to Prince George of Denmark. Grad-

ually an irreparable breach developed between Sarah and Abigail. After Harley fell from office (Feb. 1708) he contrived to negotiate with the queen through Abigail and in 1710 he arranged through her for the queen to dismiss her ministers. Abigail succeeded to the charge of the privy purse; her brother Jack became colonel and her husband was among the 12 Tory peers created in 1712 to secure approval of the treaty of Utrecht. In 1714 she deserted the earl of Oxford, accused him bitterly of being useless for the queen's service and procured his dismissal in favour of Lord Bolingbroke. After the queen's death she lived in retirement with her husband and died on Dec. 6, 1734. The fact that Abigail turned against both her patrons, the duchess of Marlborough and the earl of Oxford, has led historians to write harshly of her, but Jonathan Swift, who knew her intimately, spoke highly of her character and abilities.

The most useful work to consult on Lady Masham is W. S. Churchill, *Marlborough, His Life and Times*, 4 vol. (1933-38). (W. R. Wd.)

MASHAM, SAMUEL CUNLIFFE LISTER, 1ST BARON (1815-1906), English inventor of wool-combing and silk-combing machines, was born on Jan. 1, 1815, at Calverley Hall, near Bradford, Yorkshire, the son of a wealthy manufacturer. Starting at Manningham in 1838 with his elder brother John as spinners and manufacturers, Samuel devoted considerable attention to devising efficient mechanical wool-combing methods. He finally produced and patented a machine which performed this operation remarkably well. In time he had nine combing mills operating at once—five in England, one in Germany and three in France. In 1855 he turned his attention to finding a way of working up waste silk (i.e., the residue remaining after reeling silk cocoons). After spending about ten years and an enormous amount of money, he perfected means by which silk yarn could be made from a cheap raw material and sold at many times the cost. His velvet loom was another important textile machinery development.

He was awarded an Albert medal in 1886 and created a baron in 1891. Lord Masham died at Swinton Park, Yorkshire, on Feb. 2, 1906. (A. Dr.)

MASINISSA (MASSINISSA) (c. 240-148 B.C.), ruler of much of Africa north of the Sahara in the 2nd century B.C. He was the son of the chieftain of a Numidian tribal group, the Massyli, centred on Cirta (Constantine in northeastern Algeria). Brought up at Carthage, of which his father was an ally, he fought for Carthage against the Romans in Spain at the head of a cavalry force from 212 to 206. When the Carthaginians were driven from Spain in 206 Masinissa changed sides and promised to assist the Romans in an invasion of Carthaginian territory in Africa. To make his promise effective he returned to Numidia, where his father had died and his succession was disputed. Before he could assert his rights, his kingdom was overrun by Syphax, ruler of another substantial tribal group, the Massaesyli, extending west to the Mulucha (Moulouya) river with a centre at Siga on the river of the same name (modern Tafna); Syphax, after a brief flirtation with the Romans, had remained loyal to Carthage. Masinissa escaped with a loyal following and after joining the Romans at Utica rendered them great assistance in the next two years. In return, with Roman help he became king of both Massyli and Massaesyli after the defeat of Syphax and the Carthaginians and married Syphax's Carthaginian wife Sophonisba. This action was viewed with disfavour by the Romans; according to tradition he therefore sent her poison, with which she killed herself. He showed unconditional loyalty to Rome and his position in Africa was strengthened by a clause in the peace treaty of 201 between Rome and Carthage prohibiting the latter from going to war even in self-defense without Roman permission. This enabled Masinissa to encroach on the remaining Carthaginian territory as long as he judged that Rome wished to see Carthage weakened. By the end of his reign he had extended his kingdom as far east as the Cyrenaican border and reduced Carthaginian territory to the area northeast of a line from Thabraca (Tabarka) to Thaenae (near Sfax).

This, however, was only the outward manifestation of Masinissa's ambitious and vigorous policy. His chief aim was to build a strong and unified state from the seminomadic Numidian tribes. This involved the introduction of Carthaginian techniques, par-

ticularly agricultural, and the forcible settlement of many Numidians as peasant farmers. His respect for Carthaginian civilization was also shown by his favourable treatment of Carthaginian settlements along the north African coast which were in his territory. He probably looked forward to ruling all north Africa, including Carthage, in which there grew up a party favourable to him. Such hopes were dashed when a Roman commission headed by the elderly Marcus Porcius Cato came to Africa about 155 to decide a territorial dispute between Masinissa and Carthage. Animated probably by an irrational fear of a Carthaginian revival, but possibly by suspicion of Masinissa's ambitions, Cato thenceforward advocated, finally with success, the destruction of Carthage. Masinissa showed his displeasure when the Roman army arrived in Africa in 149, but he died early in 148 without a breach in the alliance. He was the greatest figure of native north African stock in antiquity, with a lasting influence; Rome's later achievement in Numidia was partly based on his civilizing activity.

See S. Gsell, *Histoire ancienne de l'Afrique du nord*, vol. iii, pp. 171-365 (1918). (B. H. Wa.)

MASJED SOLEYMAN (MASJID-I-SULAIMAN), the major oil town of Khuzistan *ostan* (province), Iran, lies 115 mi. N.E. of Ahvaz within the barren foothills of the Zagros mountains, at an elevation of 3,220 ft. The climate is extremely hot in summer but mild and rainy in winter. The town began to develop after oil was struck in May 1908 by William Knox d'Arcy's exploration team in the vicinity of the old village Masjid-i-Sulaiman, and production started in 1913. Pop. (1956) 44,655. About two-thirds of the employed population are in the oil business, the rest in trade and services. Labour supply comes largely from the Bakhtiari tribes. The town is a 12-mi.-long chain of clusters of workshops, pumping stations, tanks, small refineries, stores and depots, compounds of different grades, and bazaars, the only larger agglomeration being round the old village. The town is connected by asphalt road with Shushtar (37 mi.), Ahvaz (95 mi.) and the other oilfields. A pipeline carries the oil via Ahvaz to Abadan or to Bandar-e Ma'shur. (H. Bo.)

MASK is a form of covering for the face employed as a protective screen or disguise; the term also refers to a facial portrait in three dimensions. As a protective device, the mask has been used by medieval horsemen, by fencers, by welders and, in modified form, by participants in competitive athletic events. The practice of reproducing the features of memorable living or dead persons by a mask molded directly from the subject's face has been reported among ancient Phoenicians, Egyptians, Greeks and Assyrians. The Romans are reported to have invented a technique of casting in wax. During the 19th century, three-dimensional portraiture enjoyed great popularity in the United States and Europe. With liquid plaster of Paris, a negative cast of the human face could be produced which in turn acted as a mold for the positive image. The features of such notables as Henry Clay, De Witt Clinton and Presidents Adams, Madison and Van Buren have been preserved in life masks. Death masks of Newton, Cromwell, Bonaparte, Keats, Schiller, Washington, Lincoln, Beethoven and other well-known figures are in existence.

The principal use of the mask, however, has been as a device of disguise, serving: (1) as part of the paraphernalia in primitive ritual; and (2) as a convention in theatrical representation.

PRIMITIVE RITUAL

Primitive men believe that spirits govern the world. Spirits in the living and in the dead, animate and inanimate, human and bestial, real and mythological, must be cajoled, exorcised, fooled, coerced, soothed, frightened and worshipped. They must be propitiated and given concrete form by idolization. To accomplish this, elaborate rituals and ceremonies, in which masks play a dominant role, have been invented.

The origin of the mask is obscure. It may have existed first as a grotesque symbol on battle shields to frighten enemies. Some authorities point to the hunt, claiming that disguise masks were first used in stalking prey and, later, to house the slain animal's spirit in the hope of placating it. Some Africans maintain, however, that the first mask was an admonitory one. A child, re-

Clay figurine of masked Greek comedian, 3rd century B.C.

Miniature Greek mask of tragedy. Clay, 3rd century, B.C.

Twentieth-century leather *commedia dell'arte* masks, made in the Italian Renaissance tradition

Paper-mâché masks made to resemble the actors who wore them in the 1926 production of Eugene O'Neill's *The Great God Brown*

Masked musicians in a production of *The Dreaming of the Bones*, by W. B. Yeats, presented at the Abbey Theatre, Dublin

Japanese *nō* drama masks of lacquered wood

THEATRICAL MASKS

COURTESY OF (CENTRE, CENTRE RIGHT) MR CARLO MAZZONE CLEMENTI, (CENTRE LEFT) HARVARD THEATRE COLLECTION; PHOTOGRAPHS, (TOP LEFT, TOP RIGHT) GJON MILI (CENTRE, CENTRE RIGHT) THOMAS M. HILL, JR., (BOTTOM LEFT) TOM HOLLYMAN—PHOTO RESEARCHERS, INC., (BOTTOM RIGHT) PAUL HUFNER FROM SHOSTAKOVICH

Hippopotamus mask made by the Kalabari Ijo, Nigeria. This kind of mask, worn only once every 25 years, is used to honour water spirits in an elaborate pantomime ritual during which the wearer wades in chin-deep water, his mask turned skyward in imitation of a ghostly vision. Wood; 18 3/4 in. high

Totemic fish mask from the Onge Bay area of Papua, New Guinea. Painted bark cloth over a rattan frame with a fringe of dried grass 64 1/4 in.

SOME REPRESENTATIVE MASKS

Carnival mask worn by a performer in the Dance of the Conquistadores, Guatemala. Papier-mâché

Female tumbuan mask of the Dukduk secret society, New Britain. This kind of mask was worn once a month by members of the society during ceremonies in which justice was dispensed to the tribe. The head is of sacking with tuft of feathers and skirt of leaves. 4 ft. 11 in. high

Balinese mask representing the witch Rangda, from the *Tjalon-Arang* dance drama. Lacquered wood, cloth, and horsehair

Modern dance mask from Kenu on the Dahomey-Nigeria border. The carved man seated at a sewing machine on top of the mask is evidence of the influence of modern subject matter on traditional African art. Painted wood

Dance mask, representing a water demon, from New Caledonia. Cylindrical basketwork with face of blackened wood and feather fringe

Cien initiation mask from the middle Sepik region of New Guinea. Upper portion is of basketwork with faces modeled of red earth mixed with coconut oil, the mask is trimmed with shells and ossuery feathers with a skirt of bark fibers. Height 70 1/2 in.

Eagle mask made by the Kwakiuti Indians, northwest coast of North America. Strings through the eyes and the winglike side pieces to produce a frightening effect. Painted wood; breadth with side pieces extended.

Gold funeral mask, placed over the face of an unknown Mycenaean ruler. Greece; 13th century B.C.

Aztec mosaic mask, of cedar wood inlaid with turquoise and shell. The mask may be a representation of the god Quetzalcoatl. Mexico; height 6½ in.

Ashanti gold mask from the treasure of King Kofi Kobari, Ghana. A ring beneath the beard (not visible) suggests that the mask may have been a trophy of war, attached to the king's throne. Height 6¾ in.

peatedly told not to, persisted in following its mother to fetch water. To frighten and discipline the child, the mother painted a hideous face on the bottom of her water gourd. Others say the mask was invented by a secret African society to escape recognition while punishing marauders.

Primitives have designed masks of innumerable varieties from the simplest of crude "false faces" held by a handle, to complete head coverings with ingenious movable parts and hidden faces. Masklike carvings, expected to accomplish the mask function, range in size from tiny amulets to huge totem poles and house posts. Native mask makers have shown great resourcefulness in selecting and combining available materials. Among the substances utilized are woods, metals, shells, fibres, ivory, clay, horn, jade, onyx, stone, feathers, leather, furs, paper, cloth, and corn husks. Surface treatments have ranged from rugged simplicity to intricate carving, from polished woods and mosaics to gaudy adornments.

Because everything was believed to possess a spirit, it was natural for primitive man to become selective, to find authority for himself and his family by identifying with a specific nonhuman spirit. He adopted, therefore, an object of nature as the resting place for his own spirit, and mythologically tracing his ancestry back to the chosen object, he pre-empted the leopard or elephant, the hawk or serpent as the emblem of himself and his clan. This is the practice of totem, and it is the basic religious conception of the primitive hunter. He puts a taboo on his totem, forbids himself and his totem brothers to kill or eat it, makes masks to house the totem spirit, dances for it and invents ritual to honour it. The totem ancestor, he believes, actually materializes in its mask; so masks are of the utmost importance in securing protection and bringing comfort. Totemism consolidates family pride and distinguishes social lines.

The Papuans of New Guinea build mammoth totem masks attaining 20 ft. in height. Made of wood or bark cloth, these man-animal masks are given large, painted eyes and a frightening aspect. When placed against the wall of the men's secret clubhouse they serve to protect the members of the totem clan. Similar is the practice among the Indians of the American northwest coast where painted masks three or four feet long signifying the clan are placed before individual members' homes. The totem pole of the Eskimo and British Columbian Indian fulfills the same function. The African totem mask is most often carved from ebony or other hard woods, designed with graceful lines and showing a highly polished surface. Deer, antelope, gorilla, elephant, panther and leopard masks, their features elongated and beautifully formalized, are common. Generally, the South Pacific masks are more grotesque than the African, less attention being given to realism in concept or execution. Dried grass, woven palm fibres, coconuts and shells, as well as wood, are employed in the masks of New Guinea, New Ireland and New Caledonia. Represented are fanciful birds and animals with distorted or exaggerated features.

The high priest among most primitives was the *shaman* or medicine man. Frequently he had his own very powerful totem, in whose mask he could exorcise evil spirits, punish enemies, locate game or fish, predict the weather and, most importantly, cure disease. Usually, the medicine man's mask was sacred, more mythological, elaborate and fantastic than others.

The northwest-coast Indians in particular devised mechanical masks with movable parts to reveal a second face—generally a human image. Believing that the human spirit could take animal form and *vice versa*, the makers of these masks fused man and bird or man and animal into one mask. Some of these North Pacific articulating masks acted out entire legends as their parts moved. One, called the mask of the first dawn, represents night when its black wings are closed. When the wearer pulls a string and the wings open, a red, beaked sun appears; another string, and the sun mask rises on small iron rods to reveal the face of the light-maker painted white. A device on top scatters tiny feathers to represent mist or fog.

The *shaman* of the North American Pueblo Indians, the Hopi, the Zuni and Keres, is primarily concerned with rain making. Together with masked dancers representing clouds, rain spirits, stars,

Earth Mother, sky-god, etc., he takes part in elaborate ceremonies designed to assure bumper crops. Spirits, called *Kachinas*, who first brought rain to Pueblo tribes, are said to have left their masks behind when sent to dwell in the bottom of a desert lake. Their return to help bring the rain is incarnated by the masked dancer. Cylinder- and postlike masks, covering the entire head and resting on the shoulders, are of a primal type. They are made of leather, old saddles or rawhide, humanized by hair and a variety of adjuncts. Eyes are represented by incisions or by buckskin balls filled with deer hair and affixed to the mask. The nose is commonly of rolled buckskin or corncob. Frequently the mask has a projecting wooden cylinder for a bill or a gourd stem cut with teeth for a snout. Horns are attached to some masks and the datura, a flower which has the power to induce hallucinatory visions, is generally a part of the adornment. Many colours are used in their painting; plumes and beads are attached and the sex of the mask is distinguished by its shape: round head for male and square for female.

The magic of the mask has been employed extensively to cure sickness, usually by the medicine man wearing a mask representing the fever or specific disease; he devil dances the illness out of the patient into the mask. Chinese children have long been made to wear measles masks to protect them from that common ailment, and both the Chinese and Burmese have had cholera masks. The disease mask reached its zenith in Ceylon where 19 distinct disease devil masks were devised. Even deafness was thought curable by use of the mask. The Sinhalese disease masks are of ferocious aspect, fanged, and with starting eyes. Sometimes having articulating jaws and, gaudily coloured, they present a dragonlike appearance.

In some primitive cultures, secret societies, whose members were masked, could drive disease demons from entire villages and tribes. Most familiar is the False Face society of the Iroquois Indians from the American northeast coast. These professional medicants wear long-haired, grimacing, twisted masks representing the *Gahadogoka gogosa*, demons who plague the Iroquois. Violent pantomimes are performed to exorcise them. According to legend the False Face masks must be carved from a living basswood tree, so they will possess life. Permission, which is sought through incantations and ritual, must be granted by the tree.

Like disease-curing, the art of demon-chasing and of admonishing women, children and criminals has had wide practice. Discipline masks are common in China, Africa, the South seas and North America. Towering false faces, mumbo jumbo, screaming giants and identically masked men maintain order and exact punishment among tribes in the Congo. The Dukduk, a secret society in New Britain, appear in their monstrous five-foot masks once a month to police, to judge and to execute offenders.

The Dukduk, like other secret societies, also preside at initiation ceremonies, an important function throughout the primitive world. Totem and spiritualistic masks are donned at these ceremonies, and some elaborate, precious masks of gods and demons are reserved for appearance only at initiation, the most important ceremony in the male's life. The Great Cannibal Spirit dominated the Kwakiutl Indians' initiation rites in British Columbia, a strange, heavily carved wooden face with four pipelike eyes and horns and an extended pipe as mouth. Most impressive of initiation masks are the exquisitely carved human faces of the west coast Africans. Among the Bapendes of the Republic of the Congo, after a lengthy ordeal of teaching and rites of initiation, the youth appears in a mask representing the ghost of his childhood. The mask is later cast aside and replaced by a small ivory duplicate which is worn as a charm against misfortune and as a symbol of his manhood.

Ceremonies associated with the dead and with departing spirits exist in every known culture. Totem ancestors, demon spirits, benevolent shades and mythological characters are all represented by masks at funerals and spiritual festivals. Primitive men believed it necessary to entice or force spirits of the newly dead to depart for the spirit world. Money, food, means of transportation and other travel accessories were placed with the body to assist the spirit to the nether world. Obstreperous and obstinate spirits had to be exorcised with masks designed to frighten and coerce.

The Donegon tribe of Africa has a six-day funeral ritual performed by masked dancers to drive away reluctant spirits. Curiously, some of these African masks have white complexions and non-Negroid features.

Some primitives, particularly those of the South seas and Africa, set aside certain times of the year to honour and placate departed spirits. On these occasions recognizable masks of dead chieftains, relatives, foes and friends are worn or exhibited. Gifts are made to the spirits incarnated in the masks while professionals, wearing stylized mourning masks, dance the ritual. In parts of Africa spiritualism flourishes much like a sport. The youths of the tribe do not even need a funeral in order to make "juju," the practice in which the community is presented with returning spirits, in the form of masks, who exact gifts from relatives as the price for re-departure.

Burial masks to protect spirits and guide them on their way have been widely excavated. In Mycenae were found seven of beaten gold which appear to be portrait masks. Gold masks were regularly placed on the faces of dead kings in Cambodia and Siam, and burial masks of silver and gold, bronze and terra cotta have been discovered in Japan, Greece, Italy, the Crimea, Mexico, South American countries, Phoenicia, Mesopotamia, France, Britain and in the Danube valley, suggesting that similar practices were universal. For 3,000 years, the Egyptians placed a stylized, impersonal mask of painted plaster, gold or silver upon the face of important dead persons in order that the spirit might find its final resting place, the mask serving to guide the spirit back to the body. In Mexico masks were often placed upon idol statues to animate them. Made of jadeite or onyx, the Toltec and Aztec masks, whether of idols, chieftains, or village leaders, are marked by great simplicity, formalism and symbolic realism. They seem to be generic representations of the tribe rather than portraits of individuals, and they are still carved by Indian craftsmen. Masks made from skulls have been found in Mexico and in Melanesia. Believing that the skull was the home of the spirit, the Aztecs took great care of those inhabited by important personages. Like their wooden masks, the Aztec skull masks are inlaid with turquoise mosaic bands alternating with bands of lignite. Eye sockets were filled with pyrites, and holes were drilled in the back so the mask might be hung as an idol.

In Melanesia ornamented skull masks were often hung in front of a dead man's statue to give it life, just as ashes of a dead Alaskan chief were put in the abdominal hole of his ancestor post to animate it and give it potency.

Among the special uses of masks other than those mentioned are the widely used war masks, worn not for protection but to frighten the foe. War masks are now ordinarily worn only in dances and rituals, especially among the Africans, Javanese and northwest coast Indians. The primitives of New Ireland devised "peace masks" worn at victory festivals in which even the enemy participated.

Still another special mask is the Dionysiac mask of fertility. Often out-and-out clowns such as the "Mud Heads" of the American Pueblos, masks of this sort are common in *fiestas* and are among the forerunners of Halloween, Mardi gras and other festival masking. Ludicrous, grotesque or superficially horrible, festival masks are usually conducive to good-natured licence, release from inhibitions, and ribaldry.

Not to be overlooked are the masks used throughout Mexico for storytelling and caricature, such as those seen in the Dance of the Old Men and the Dance of the Moors and the Christians. Many "art for art's sake" masks, made with no religious connotations but simply for decorative purposes, are made available to tourists. Japan and Mexico, Kenya and Indonesia are among the leading producers of these handsome artifacts.

THEATRE

Greek and Roman.—The mask as a device for theatre first emerged in western civilization from the religious practices of ancient Greece. In the worship of Dionysus, god of fecundity and the harvest, the communicants' attempt to impersonate the deity by donning goat skins and by imbibing wine eventually developed

into the sophistication of masking. When a literature of worship appeared, a disguise, which consisted of a white linen mask hung over the face (a device supposedly initiated by Thespis), enabled the leaders of the ceremony to make the god manifest. Thus symbolically identified, the communicant was inspired to speak in the first person, thereby giving birth to the art of drama. In Greece the progress from ritual to ritual-drama was continued in the highly formalized theatrical representation, which, although still concerned with religious and semireligious subjects and performed in connection with religious exercises, was maintained by the state and performed by professionals and is understood as the beginning of secular drama in the west. Masks used in these productions became elaborate headpieces made of leather or painted canvas and depicting an extensive variety of personalities, ages, ranks and occupations. Heavily coiffured and of a size to enlarge the actor's presence, the Greek mask seems to have been designed to throw the voice by means of a built-in megaphone device and, by exaggeration of the features, to make clear at a distance the precise nature of the character. Moreover, their use made it possible for the Greek actors—limited by convention to three speakers for each tragedy—to impersonate a number of different characters during the play simply by changing masks and costumes.

In his encyclopaedia, *Onomasticon*, Julius Pollux, Greek sophist and grammarian of the 2nd century A.D., described in detail the catalogue of comic and tragic masks used in the earlier Greek theatre, but no clear visual picture of these masks emerges. Several manuscripts of the plays of Terence contain illustrations of masks used by comic actors of the Roman theatre, a theatre heavily influenced by the style and practices of the Greek. Their comic mask appears to have been a grotesque affair with the mouth fashioned in the form of a huge bivalve generally fringed with a stylized beard. Details from frescoes, vase paintings and fragments of stone sculpture complete what is known of these ancient theatrical masks. The tendency of the early Greek and Roman artists to idealize their subjects throws doubt, however, upon the accuracy of these reproductions. Some authorities, such as Olive L. Riley, maintain that the masks of the ancient theatre were crude affairs with little aesthetic appeal.

Medieval.—After the interval of the Dark Ages, the mask makes its appearance again in the mystery plays of the late middle ages. In plays dramatizing portions of the Old and New Testaments, grotesques of all sorts, such as devils, demons, dragons and personifications of the seven deadly sins, were brought to stage life by the use of masks. But again, no reliable pictorial record has survived. Costume and property lists for the English cycle plays contain scattered references. For example, the Norwich *Creation* play notes "a face [mask] and hair for the Father." Other references suggest that Lucifer wore a false head painted black and that actors impersonating God and probably Christ had masks covered with gilt. Masks used in connection with present-day carnivals and Mardi gras and those depicting dragons still used by Tyrolean peasants are most likely the inheritors of the tradition of medieval masks. Constructed of papier-mâché, the masks of the mystery plays were evidently marvels of ingenuity and craftsmanship, being made to articulate, and to belch fire and smoke from hidden contrivances.

Renaissance.—The Renaissance in Italy witnessed the rise of a theatrical phenomenon that spread rapidly to France, to Germany and to England, where it maintained its popularity into the 18th century. Comic plays improvised from scenarios based upon the domestic dramas of Plautus and Terence and upon situations drawn from anonymous Roman mimes flourished under the title of *commedia dell'arte* (q.v.). Adopting the Roman stock figures and situations to their own usages, the players of the *commedia* characterized types such as Pantalone, Dottore, El Capitano, young lovers and a variety of *Zanni* with such names as Arlecchino, Brighella, Scaramuccia, Scapino, Pedrolino and Pulcinella. Most of these characters were masked. Sometimes the masking was grotesque and fanciful; but generally a heavy leather mask, full or half face, with beaked nose and wrinkles, with a wart on the forehead to distinguish particular *Zanni*, disguised the *commedia* player. Excellent pictorial records of both *commedia* costumes and masks

exist; some sketches show Harlequin and Colombina wearing black masks covering merely the eyes from which the later masquerade mask is certainly a development. Mask making has remained a fine art in Italy.

Modern.—Except for vestiges of the *commedia* in the form of puppet and marionette shows, the drama of masks all but disappeared in western drama during the 18th, 19th and first half of the 20th centuries. In revivals of Greek plays masks have occasionally been employed, and such plays as Gerhart Hauptmann's *The Sunken Bell* and dramatizations of *Alice in Wonderland* have required masks for the performers of grotesque or animal figures. But the mask as a convention has lost its importance. W. B. Yeats revived the convention in his *The Dreaming of the Bones* and in other plays patterned upon the Japanese *nô* drama, and in 1926 theatregoers in the United States witnessed a memorable use of masks in Eugene O'Neill's *The Great God Brown*, wherein actors wore masks of their own faces to indicate changes in the internal and external lives of their characters.

Japanese.—In many ways akin to the Greek drama in origin and theme, the *nô* drama (*q.v.*) of Japan has remained a significant part of national life since its beginnings in the 14th century. Inspired by the Buddhist priests of the Zen sect and by the pleasure-loving Shogun Yoshimitsu, 210 *nô* dramas are still in existence. The *nô* mask, of which there are about 125 named varieties, are rigidly traditional and are classified into five general types: old persons (male and female), gods, goddesses, devils and goblins. The material of the *nô* mask is wood with a coating of plaster lacquered and gilded. Colours are traditional. White is used to characterize a corrupt ruler; red signifies a righteous man; a black mask is worn by the villain who epitomizes violence and brutality. *Nô* masks are sharply characterized and exquisitely carved by highly respected artists known as *Tenka-ichi*, "the first under heaven." Tranquility, wrath, cunning and mirth, as well as more subtle shades of feeling, are portrayed with beautifully sublimated realism. It is said of these masks that when in movement they appear to change in expression.

Tibetan.—In Tibet, sacred dramas illustrating the former births of Buddha and similar events are performed by masked lay actors. A mystery play with manifestations of gods and demons by awe-inspiring masks is performed exclusively by the priests or Lamas at fixed seasons of the year and is still called "Dance of the Red Tiger Devil." This play appears to have been originated by a devil-dancing cult and is performed for the exorcising of demons. Masks employed in this play are made of papier-mâché, cloth and occasionally gilt copper. In Sikkim and Bhutan, where wood is abundant and the damp climate destructive, they are carved of durable wood; in all cases they are fantastically painted and provided with a wig of yaktail in various colours. They take the forms of hideous tusked ogres, animals, ghouls and skeletons; the jester or buffoon has a blue mask and cowls.

Chinese.—Masks, usually made of papier-mâché, are employed in the religious or admonitory drama of China, but for the greater part the actors in popular or secular drama make up their faces with cosmetics and paint to resemble masks. The sacred drama, which in China is highly didactic, is peopled with devils, madonnas, kings and court attendants of the ten purgatories; all are masked fancifully and grotesquely. Akin to this "morality" drama are the congratulatory playlets, pageants, processions and dances of China. Masks employed in these ceremonies include animal gods, sky-gods, mythological heroes, dragon kings and ancestors. They are highly ornamented masks, with jeweled and elaborately filigreed headgears. In the lion dance of both China and Japan, a red mask of a lion is carried on a pole by itinerant players whose bodies are concealed by a dependent red cloth. The mask and cloth are manipulated violently, as if the animal were in pursuit, to the taps of a small drum. The lower jaw of the mask is movable and is made to emit a loud continuous clacking by means of a string.

Javanese.—In Java, wooden masks, *tupeng*, are used in certain theatrical performances that are extremely popular. These plays developed from the shadow puppet plays of the 18th century and are performed not only as amusement but as a safeguard against

calamities. The stories are in part derived from ancient Sanskrit literature, the Mahabharata and the Ramayana, although the Javanese are now Muslims. The masks are ordinarily held in the teeth by means of a strap of leather or rattan fastened across the inside. Occasionally an actor interrupts the unseen Dalang who is speaking the play. The mask is then held in front of the face while the player says his line. The use of masks in Java is exceptional; for masks, being forbidden under the prohibition of images, are practically unknown in the Islamic east. See also references under "Mask" in the Index.

MASK, LOUGH (LOC MEASIA), a lake which, like Lough Corrib (*q.v.*), 3 mi. S., has the Irish Central lowland to the east and the towering mountains of Connaught to the west. It is mainly 4 to 5 mi. wide, with offshoots into the mountain valleys, and 10 mi. long. Some of its shores are marshy pastures, but there are also small hills of well-drained soils, known as drumlins, all of which are farmed. The lake, 62 ft. above sea level, receives the drainage of the smaller Lough Carra, at 69 ft., and of various rivers. In the 19th century a canal was dug to connect Mask with Corrib but all the water sank through the limestone. Lough Mask is 191 ft. deep, perhaps owing to the scouring action of ice, though its origin is mainly due to solution of the limestone so widely developed in this western part of the Irish lowland. Beside a ruined castle on the lake shore, a few miles southwest of Ballinrobe, is Lough Mask house, famous as the residence of Capt. Charles Cunningham Boycott (*q.v.*). (T. W. FR.)

MASKELYNE, NEVIL (1732-1811), 5th English astronomer royal, whose chief aim was the practical improvement of the art of navigation, was born in London on Oct. 6, 1732. He was educated at Westminster school and Trinity college, Cambridge, where he graduated as 7th wrangler in 1754. He was ordained in 1755, but his interest in astronomy had been aroused by the eclipse of July 25, 1748, and in 1761, on James Bradley's recommendation, he was deputed by the Royal society to observe the transit of Venus in St. Helena. During the voyage he experimented upon the determination of longitude by the method of "lunars," and introduced this method into navigation by publishing, in 1763, *The British Mariner's Guide*. In 1765 Maskelyne succeeded Nathaniel Bliss as astronomer royal. In 1766 he published the first volume of the *Nautical Almanac*. He continued the superintendence of this, his greatest work, until his death on Feb. 9, 1811.

Maskelyne's first contribution to astronomical literature was "A Proposal for Discovering the Annual Parallax of Sirius," published in 1760 (*Phil. Trans.*, li, 889). Subsequent volumes of the same series contained his observations of the transits of Venus (1761, 1769), on the tides at St. Helena (1762) and on various astronomical phenomena at St. Helena (1764) and at Barbados (1764). In 1772 he suggested to the Royal society the famous Schiehallion mountain experiment for the determination of the earth's density, and he carried out his plan in 1774. From Maskelyne's observations Charles Hutton deduced a density for the earth 4.5 times that of water.

MASKS, GAS: see GAS MASK.

MASOLINO DA PANICALE (TOMMASO DI CRISTOFORO FINI) (1383-after 1435), one of the principal Florentine painters of the early Renaissance, was born at Panicale near San Giovanni Valdarno in 1383. He thus came from the same district as his younger contemporary Masaccio (*q.v.*), with whom his career was closely linked. Trained in a Florentine studio, possibly that of Gherardo Starnina, he appears before 1407 to have been a member of the workshop of Lorenzo Ghiberti. He was enrolled in the Arte dei Medici e Speziali in Florence in 1423. In 1424 he received payment for frescoes in S. Stefano at Empoli (in large

part destroyed); a half-length "Virgin and Child With Two Angels" in S. Stefano and a "Pietà" in the Collegiata at Empoli also date from this time. A panel of the "Virgin and Child" in the Alte Pinakothek at Munich was probably painted before 1420, and a "Virgin and Child" in the Kunsthalle at Bremen is dated 1423.

The earliest work executed in collaboration by Masolino and Masaccio, a "Virgin and Child With St. Anne" (Uffizi, Florence), painted about 1420, illustrates the fundamental antithesis between the decorative late Gothic style of Masolino and the more progressive style of his pupil Masaccio. In this work Masolino was responsible for the cartoon and for executing the figures of St. Anne and four of the five angels.

A double-sided altarpiece for Sta. Maria Maggiore in Rome (now distributed between the Pinacoteca Nazionale in Naples, the Philadelphia Museum of Art and the National gallery, London) seems also to have been commissioned from Masolino about 1424 and was executed in conjunction with Masaccio. The two central panels of this altarpiece, representing the foundation of Sta. Maria Maggiore and the Assumption of the Virgin, are Masolino's most distinguished panel paintings.

The influence on Masolino of the stronger and more decisive personality of Masaccio reached its climax in the frescoes of scenes from the life of St. Peter in the Brancacci chapel in the church of the Carmine in Florence. There have been many opinions about the respective shares of the two artists in this important cycle. It is likely that the frescoes were commissioned from Masolino about 1425 and that at this time he painted some lost scenes in the upper register of the chapel walls. Thereafter he worked in Hungary, from which he returned in 1427 to undertake, jointly with Masaccio, the remaining frescoes in the chapel. By this time the balance of emphasis within the studio had shifted toward Masaccio, and Masolino was responsible for only one fresco, that of "St. Peter Preaching," on the altar wall and three scenes on the right wall, the "Fall of Adam and Eve," the "Healing of the Lame Man" and the "Raising of Tabitha," where the perspective scheme seems to have been worked out and in part realized by Masaccio. The figures in the latter fresco reveal Masolino as an artist of great suavity and as a consummate colourist.

Work on the Brancacci frescoes was abandoned in 1428, and probably at this time Masolino received the commission for a fresco cycle in the Branda chapel in S. Clemente in Rome. The death of Masaccio in Rome in the autumn of 1428 marks a turning point in Masolino's career, and the story of his later development is that of a progressive return to the international Gothic idiom of his youth. This is evident initially in the S. Clemente frescoes (where the space construction is once more decorative) and subsequently in a frescoed "Virgin and Child" in S. Fortunato at Todi (1432) and in fresco cycles in the Baptistery and Collegiata at Castiglione d'Olena (Lombardy). The decoration of the Baptistery (which contains scenes from the life of St. John the Baptist) was completed in 1435, and makes use of the same deep but imperfectly systematized space constructions as the S. Clemente frescoes. The extensive panoramas in the backgrounds of the "Crucifixion" on the altar wall in S. Clemente and the "Baptism of Christ" at Castiglione d'Olena are milestones in the history of landscape painting. An important landscape fresco by Masolino also exists in the Palazzo Castiglione at Castiglione d'Olena. With their light tonality and elegant, rhythmical figures, the scenes by Masolino in the Baptistery and Collegiata form two of the most fascinating fresco cycles of the 15th century. Like the sculptor Ghiberti, Masolino achieved a compromise between the Gothic past and the advanced style of his own day, and owes his prominence in the history of Florentine art not to his innovations but to his lyrical style and his unflinching artistry. Masolino's death is generally assigned to the year 1447, but may have occurred at any time after 1435.

See P. Toesca, *Masolino da Panicale* (1908); M. Salmi, *Masaccio* (1948).

MASON, the name of a distinguished family of U.S. musicians in the 19th and early 20th centuries.

LOWELL MASON (1792-1872) was a pioneer of musical education in the U.S. and a composer of hymn tunes. Born at Medfield, Mass., on Jan. 8, 1792, he founded the Boston Academy of Music

in 1832 and later trained music teachers. He promoted festivals of choral music and published many successful song collections and hymns; among the latter, "Nearer My God to Thee" became famous. He died at Orange, N.J., on Aug. 11, 1872.

WILLIAM MASON (1829-1908), son of Lowell Mason, was born at Boston, Mass., on Jan. 24, 1829. He was a pupil of Ignaz Moscheles and Liszt and became known as a concert pianist, piano teacher and composer of light piano pieces. He died in New York city on July 14, 1908.

DANIEL GREGORY MASON (1873-1953), a grandson of Lowell Mason and nephew of William Mason, was born at Brookline, Mass., on Nov. 20, 1873. His father, Henry Mason, was a co-founder of the firm of Mason and Hamlin, piano manufacturers. Daniel Gregory Mason studied with John K. Paine at Harvard university and later took lessons from Vincent d'Indy in Paris. In 1910 he joined the faculty of Columbia university and taught there until his retirement in 1942. His music was written in the manner of the German romantic composers but it also employed devices of French impressionism and Russian modernism. He wrote three symphonies, a festival overture *Chanticleer*, chamber music and several books of essays and teaching guides. He died on Dec. 4, 1953, at Greenwich, Conn.

See W. Mason, *Memories of a Musical Life* (1901); D. G. Mason, *Music in My Time, and Other Reminiscences* (1938). (N. Sz.)

MASON, GEORGE (1725-1792), author of the Virginia constitution of 1776 with its influential declaration of rights, and member of the federal Constitutional Convention of 1787, was born in Fairfax county, Va., in 1725. His father died when George was ten years old, leaving him in the care of his mother and John Mercer, a relative and a prominent attorney. As the eldest son he inherited the family estate but received little formal education. He was privately tutored and read law in Mercer's office but did not take up law as a profession, preferring the life of a planter.

As a landowner and near neighbour of George Washington, Mason took a leading part in local affairs, serving as vestryman of Truro parish and justice of Fairfax county. He became deeply interested in the Ohio company, which had been organized in 1748 by his friends and neighbours to develop trade and sell land on the upper Ohio river. At about the same time Mason helped to found the town of Alexandria, Va. In 1759 he was elected to the Virginia house of burgesses; except for his membership in the Constitutional Convention of 1787, this was the highest office he ever held—yet few men did more to determine the original shape of American political institutions.

A leader of the Virginia patriots on the eve of the American Revolution, Mason served on the committee of safety and in 1776 drafted the constitution for Virginia, his declaration of rights being the first authoritative formulation of the doctrine of inalienable rights. Mason's work was known to Thomas Jefferson and influenced his drafting of the Declaration of Independence. Mason's model was soon followed by most of the other states and was also incorporated, in a watered-down form, into the federal constitution. He was a member of the Virginia house of delegates from 1776 to 1788.

As a member of the Philadelphia Constitutional Convention of 1787, Mason strenuously opposed the compromise permitting the continuation of the slave trade until 1808. Because of this and because he objected to the large and indefinite powers vested in the new government, he joined Patrick Henry and Richard Henry Lee in opposing adoption of the federal constitution. A Jeffersonian Republican, he believed that local government should be kept strong and central government weak. His criticism of the proposed new constitution helped bring about adoption of the Bill of Rights, as the first ten amendments came to be known. Mason declined election to the senate and retired to his home, Gunston Hall, where he died on Oct. 7, 1792.

See K. M. Rowland, *The Life and Writings of George Mason* (1892); H. D. Hill, *George Mason; Constitutionalist* (1938). (T. P. A.)

MASON, JAMES MURRAY (1798-1871), U.S. political leader, whose seizure with John Slidell precipitated the famous "Trent affair" during the American Civil War, was born in

Fairfax county, Va., on Nov. 3, 1798. He was a member of the Virginia house of delegates (1826-32), of the state constitutional convention of 1829, of the national house of representatives (1837-39) and of the U.S. senate from 1847 until the outbreak of the Civil War when he resigned to take part in the Virginia secession convention. A staunch Democrat, he upheld state's rights and slavery and was the author of the Fugitive Slave act of 1850.

In Aug. 1861 he was appointed commissioner of the Confederate states to Great Britain. The British ship "Trent," upon which he and John Slidell, the commissioner to France, sailed, was intercepted by a U.S. ship-of-war, and the two commissioners were seized and carried as prisoners to Boston but were released two months later through the demands of Great Britain. Arriving at London, Mason was unable to secure official recognition, and his commission to Great Britain was withdrawn late in 1863.

He died at Alexandria, Va., on April 28, 1871.

See Virginia Mason, *The Public Life and Diplomatic Correspondence of James M. Mason, with some Personal History* (1903).

MASON, JOHN (1586-1635), founder of New Hampshire, was born in King's Lynn, Norfolk, Eng. He was governor of the English colony in Newfoundland (1615-21) and published the first map of that region. In 1622 he obtained from the council for New England a grant of the territory (Mariana) between the Salem and Merrimack rivers, and with Sir Ferdinando Gorges, a grant of the region between the Merrimack and Kennebec rivers extending 60 mi. inland (Province of Maine).

In 1629 Mason and Gorges agreed upon a division of their joint holdings, Mason receiving the tract between the Merrimack and the Piscataqua, which he named New Hampshire. With Gorges and a few associates, he also secured a grant of the region named Laconia, including Lake Champlain, and in 1631 the Piscataway grant, bordering on the Piscataqua river.

He was vice-president of the council for New England in 1632, and in 1635 was appointed vice-admiral for New England, but died in London in Dec. 1635, before he could return to North America. He was buried in Westminster abbey.

See *Captain John Mason, the Founder of New Hampshire*, published by the Prince Society (1887).

MASON, JOHN YOUNG (1799-1859), U.S. political leader and diplomat who helped frame the Ostend manifesto (*q.v.*) calling for the annexation of Cuba by purchase or war, was born in Greensville county, Virginia, on April 18, 1799. He served in the Virginia house of delegates (1823-27), the national house of representatives (1831-1837), and as judge of the U.S. district court for Virginia (1837-44). From 1844 to 1849 he was a member of the cabinets of Presidents Tyler and Polk, as secretary of the navy, and served for a time as attorney general. He was president of the Virginia constitutional convention of 1850, and from 1853 was minister to France. In 1854 Mason joined with James Buchanan and Pierre Soulé, ministers to Great Britain and Spain respectively, in drawing up the manifesto, which was disavowed by the U.S. state department. He died at Paris, Oct. 3, 1859.

MASON, MAX (1877-1961), U.S. mathematical physicist and educator, president of The University of Chicago from 1925 to 1928, was born at Madison, Wis., on Oct. 26, 1877. He completed his undergraduate work at the University of Wisconsin in 1898 and received the Ph.D. degree from the University of Göttingen in 1903. His special interests and contributions lay in mathematics (differential equations, calculus of variations), physics (electromagnetic theory), invention (acoustical compensators, submarine detection devices) and administration of universities and foundations. Following brief appointments in mathematics at the Massachusetts Institute of Technology and Yale university, Mason taught mathematical physics at the University of Wisconsin (1908-25). In 1925 he turned to administration, first as president of The University of Chicago, then as director of natural sciences of the Rockefeller foundation (1928-29) and as president of the foundation (1929-36). In 1936 he joined the California Institute of Technology as chairman of the observatory council and member of the executive council, retiring in 1949, and later taught at Claremont (Calif.) Men's college. He died at Claremont on March 23, 1961.

(J. G. H.)

MASON, WILLIAM (1725-1797), English poet, friend and first editor of Thomas Gray, was born in Hull, Feb. 23, 1725, and educated at Hull grammar school and St. John's college, Cambridge. At Cambridge he published *Musaeus* (1747), a lament for Pope, and in 1749 was made a fellow of Pembroke college through the influence of Gray, whom he admired. Mason's poem *Isis* (1749), attacking Jacobitism in Oxford university, provoked Thomas Warton's *Triumph of Isis* (1749), generally considered superior. His two pseudoclassical plays *Elfrida* (1752) and *Caractacus* (1759) were performed in 1772 and 1776 respectively. Horace Walpole called *Caractacus* "laboured, uninteresting and no more resembling the manners of Britons than of Japanese": Gray wrote that he had read it "not with pleasure only but with emotion." Gray also said that Mason, whose verses he corrected and whom he nicknamed "Scroddles," "reads little or nothing, writes abundance, and that with a design to make a fortune by it."

Ordained in 1754, Mason received many preferments, including a canonry of York and a royal chaplaincy (1757-73). On Gray's death in 1771 Mason, his literary executor, began to edit and in 1775 published *Memoirs . . . and Poems of Mr. Gray*, including only such poems as he thought fit for a definitive edition. Contemporaries described this as an "inimitable edition," "a new species of biography," but modern editors have condemned his silent mutilation of Gray's letters. He had been helped by Walpole, with whom he corresponded regularly until 1784, when they quarreled, but the correspondence was later renewed. Mason died at Aston, April 5, 1797. His collected works, in four volumes, were published in 1811; his correspondence with Gray was edited by J. Mitford in 1853.

See W. S. Lewis (ed.), *H. Walpole's Correspondence*, vol. 28 and 29 (1955); J. W. Draper, *W. Mason* (1925).

MASON AND DIXON LINE, the boundary in the United States between Maryland and Pennsylvania, popularly regarded as the dividing line between the north and the south, although it does not extend west of the Ohio river. The line was drawn by two English surveyors, Charles Mason and Jeremiah Dixon, in 1763-68, to settle a lengthy dispute between the Penns and the Baltimores, proprietors respectively of Pennsylvania and Maryland. The dispute arose over conflicting claims to the territory from the Delaware river westward. In 1632 Lord Baltimore had been given the land north of Virginia to that point "which lieth under the Fortieth degree of north latitude" and westward to the source of the Potomac. In 1681 William Penn had been granted the area between 43° N. and a line extending westward from "a Circle drawne at twelve miles distance from New Castle . . ." to "the beginning of the fortieth degree. . . ." In 1682 Penn received a grant in the Delaware peninsula, which Baltimore claimed.

In 1685 the crown ordered this territory divided equally, the western half going to Baltimore. After years of bitter controversy Lord Chancellor Hardwicke ruled (1750) that the southern boundary of Pennsylvania should be a line running westward from the point at which the line dividing the Delaware peninsula was tangential to a circle with a radius of 12 mi. from the centre of Newcastle. Mason and Dixon resurveyed the Delaware tangent line and the Newcastle arc and in 1765 began running the east-west line from the tangent point, at approximately 39° 43'.

Along this line the surveyors set milestones brought from England, every fifth stone in the eastern portion a "crown stone" bearing the arms of Penn on one side and of Baltimore on the other. The 233-mi. line was completed in 1768 at a cost of \$75,000. In 1779 Pennsylvania and Virginia agreed to extend the line westward to a point five degrees from the Delaware river, a line running north from that point to be the westward boundary of Pennsylvania.

(H. L. S.)

MASON BEE, the name given generally to several genera of bees of the subfamily Osmiinae (family Megachilidae), which construct earthen cells, sometimes mixed with sand, pebbles or wood, each cell containing a single egg, together with honey and pollen as food for the larva. These bees are called solitary to distinguish them from the social Hymenoptera. See BEE; HYMENOPTERA.

MASON CITY, a city of north-central Iowa, U.S., the seat of Cerro Gordo county, is located on the Winnebago river, midway between Des Moines and the twin cities of Minneapolis-St. Paul, Minn. An 80-mi. radius of rich corn belt farm land produces large quantities of livestock, dairy products, poultry, eggs and a variety of farm crops.

The school system includes Iowa's first and largest junior college, Mason City junior college, founded in 1918. There are 270 ac. of public parks and two golf courses. Excellent recreational facilities are also found at Clear lake and at two state parks 10 mi. W. There are adequate accommodations for tourists and conventions.

Underlain by deposits of clay and limestone 30 ft. deep, and with sand and gravel available, Mason City supports a substantial cement industry and has one of the largest brick and drain tile plants west of the Mississippi. Other industries include meat packing, beet-sugar refining, creameries, soybean processing, fertilizer processing, millwork, founding and natural gas and gasoline pipelines.

Mason City owes its name to settlement (1853) by Freemasons. First platted in 1855, it was incorporated as a town in 1870 and as a city in 1881. For comparative population figures see table in IOWA: Population. (Hu. H. S.)

MASONRY, the craft of building with stone. The English word "mason" is from the French, which appears in two forms, *machun* and *masson* (from the last comes the modern French form *maçon*, which means either "bricklayer" or "mason"). This article deals with the history of masonry and illustrates the work of the craftsman and his tools, the machinery and processes used in modern masonry production, technical terms and types of stone.

HISTORY

The period at which wrought stone was first used architecturally is quite unknown; the earliest records of masonry worthy of the name are found in the ancient temples of Egypt, Chaldea, Phoenicia, India, China, Babylon, Assyria and Crete.

The remains of the Egyptian pyramids and vast temples are proof that the craft of masonry was in a very advanced state, hardly to be surpassed by modern craftsmen. The skill of the early Egyptian masons was quite incredible. For example, the masonry joints of the stones on the great pyramid of Khufu are under 1/100 in. thick, and some of the stones weigh up to 60 tons. Their great size and the fact that they were quarried about 140 mi. from the site indicate that vast armies of labourers were employed on the pyramid's construction, which, it has been calculated, required the continuous labour of 100,000 men for more than 20 years.

From Egypt the craft of masonry passed into Phoenicia, Asia Minor, the Aegean Islands and Greece. Greece developed the mason's craft and gradually the three well-known orders of architecture, Doric, Ionic and Corinthian, were evolved, culminating in the buildings on the Acropolis at Athens around 450 B.C. (See ORDER.) In this period we find the highest standard of masonry. The Greek architectural style, as that of Egypt, is known as *trabeated*; i.e., horizontal beams and upright posts. The arch was known at this time but never used above ground.

The Romans had little original architectural style and copied Greek forms but used stone for surface, nonconstructional treatment. However, they developed the Etruscan semicircular arch, the vault and the dome, which enabled them to increase the open span of their buildings. Being a practical people, they devised institutions, known as *collegia*, to foster and protect their arts and crafts, including masonry. These *collegia* are believed to be the parent bodies from which medieval trade guilds derived their origin. The Roman conquest of Britain probably began the history of real masonry in England, and the spirit of building encouraged by the Romans so increased the numbers of masons that in A.D. 296 the rebuilding of the city of Autun in Gaul was chiefly carried out by craftsmen from Britain and at the end of the 3rd century British masons were used in the rebuilding of Constantinople.

With the departure of the Romans from Britain in the early 5th

century A.D. and under the domination of the Saxon invaders, the use of wrought stone for building was discontinued, and it was not until about 200 years later with the revival of Christianity that efforts were made to reintroduce the craft of masonry. Masons from Italy and France were induced to come to Britain to re-establish the craft. In 926 King Aethelstan granted a charter to the masons at York, and in the reign of Henry II no fewer than 157 abbeys, priories and other religious buildings were erected. This period saw the beginning of the Gothic style of building, which reached its zenith during the 14th and 15th centuries. The many beautiful cathedrals built then are evidence of the supreme skill of the craftsmen of that time, and undoubtedly the climax of the mason's craft was the introduction of the fan vault where the stonework hangs down like stalactites in inverted cone shapes. One of the finest examples of vaulting in the world can be seen in Henry VII's chapel in Westminster abbey, London.

From the 15th century onward stone was used extensively as a building material and masonry played an important part in an expanding building program. The introduction of large-scale brick production reduced the demand for stonework, but it opened up another field for masonry in the form of stone dressings in brick façades, the best examples being perhaps in Georgian architecture. Brick was also used, and indeed still is, as a backing to masonry in solid-wall construction. (See BRICKWORK.) In time stone became an ornamental veneer and not a constructional part of the building.

In modern construction, where steel or reinforced concrete forms the frame of the building, masonry is essentially a thin veneer, supported on the frame. With style tending toward plain and unadorned façades, the need of the mason's craft has been reduced. Much work can be produced by machines and indeed, were it not so, the high cost of working stone manually would prohibit its use almost completely. There still is, however, a demand for skilled masons. In fashioning stone it is not possible to mechanize every operation, however plain the work may be, and there is always repair and maintenance work to be carried out on historical and similar buildings. This work, particularly, requires skilled craftsmanship, if the heritage left by earlier generations of builders is to be preserved.

APPRENTICESHIP AND TRAINING

The skill essential to a good mason can only be acquired through years of practice. The requirements are a sound basic education, manual dexterity, an "eye" for line and contour and an aptitude for creative work.

Initial training in most countries is by apprenticeship for a period of five years. Under the British National Apprenticeship scheme, for example, boys usually enter the trade from school at the age of 15 or from technical college at 17, and one day and two evenings a week are then spent at technical school where the apprentice pursues studies in workshop practice, building construction, craft science, solid geometry and draftsmanship. His practical training with the master mason includes, in addition to working stone, the use of machines and mechanical aids, fixing the worked stones on the building and instruction in the drawing office and setting-out shop.

The apprentice is encouraged to take the craft examinations set by the City and Guilds of London institute, after which he has a wide choice of further studies and examinations fitting him for foremanship or management responsibility within the building industry.

MASONS' TOOLS

There is a great variety of masons' tools according to the type of stone to be worked. For convenience they may be classified under five heads: granite tools; hard-stone tools; soft-stone tools; marble tools; and fixing tools. Certain of the tools are common to two or more of the classifications.

Masons tend to specialize on particular types of stone depending on the locality of their initial training. A mason from the granite districts, for instance, would not ordinarily be trained to work on hard stone or soft stone. A mason trained on hard stone would

get some instruction on working soft stone, but he would not be expected to work granite. A marble mason is usually trained on that material only and develops a technique which would be unsuitable for either granite, hard stone or soft stone. Some masons are competent on all classes of stone, but they are the exception rather than the rule. Fixers are mostly masons who, having trained with the tools, then specialize on the fixing of worked stone on the building.

The following descriptions are of tools normally used by masons, but inevitably each craftsman accumulates special tools for carrying out difficult operations such as intersections and undercut moldings.

Hammer.—This is made in various sizes and weights. The weight for granite is about three pounds; for hard stone between four and six pounds; for marble about two pounds. The head is of cast steel and the striking face inclines toward, instead of being parallel to, the handle. A malleable iron hammer, used in conjunction with "cup-headed" chisels for carving, letter-cutting and delicate enrichments, has a short head and large striking faces. A spall hammer, used for removing large quantities of rough stone and also for breaking up stones, has faces that are concave to form cutting edges; it is made of cast steel and weighs from 10 to 15 lb.

Mallet.—This is made of hickory or beech wood or sometimes of selected pear wood. It is used in conjunction with mallet-headed chisels and weighs from three to six pounds. It forms a very important item of a mason's kit and a good mallet will last almost a lifetime and is a prized possession (fig. 1[B]).

FIG. 1.—EXAMPLES OF MASONS' TOOLS: (A) DUMMY; (B) MALLET; (C) PATENT AXE OR BUSH HAMMER; (D) LEWISING TOOL; (E) JUMPER FOR GRANITE; (F) STAR JUMPER; (G) POINT, OR CLOURER; (H) WASTER; (I) CLAW CHISEL; (J) DRAG; (K) COCKS' COMBS

Dummy.—This is for use with wooden-handled chisels on soft stone and is made of a mixture of zinc and lead. Dummies are made in different weights up to three pounds (fig. 1[A]).

Axe.—This tool is used on granite for reducing surfaces to the correct level. It is made of cast steel and has a long handle for two-handed operation (fig. 1[C]).

Patent Axe or Bush Hammer.—This is used on granite to form the final or "dressed" surface. The head is fitted with a series of four to ten chisel plates and, according to the grading of these plates, different types of finish are obtained; i.e., fine axed, medium axed, etc. (fig. 1[D]).

Hammer-Headed Tools.—These tools are used in conjunction with the mason's steel hammer in working granite, marble and hard stone. They are made of cast steel and in various sizes.

The **punch** is used for roughly shaping a stone prior to tooling. When sharpened for granite or marble it is drawn out to a definite point, but for use on hard stone a narrow cutting edge is formed instead of a point. The **drafting chisel** is usually $\frac{1}{4}$ in. to

1 in. wide and used for working drafts or margins on a stone preparatory to punching and tooling. The **pitching tool** is made with a beveled cutting edge and in various widths and weights. It is for cutting off superfluous stone in fairly large pieces. The **lewising tool** (fig. 1[E]) is made in the form of a mortising chisel, the cutting edge being wider than the stem. It is used for forming undercut slots to accommodate the two-legged or three-legged type of lifting lewis. The **quirking tool** is similar in design to lewising tools, but small and lighter. The cutting edge ranges from $\frac{1}{4}$ to $\frac{1}{2}$ in. wide, and the tool is used for cutting narrow grooves. **Jumpers** (fig. 1[F] and 1[G]), two tools, are used for forming holes in stone. They are lifted and turned with one hand and struck with the hammer after each turn. The type shown in fig. 1(F) is mainly used on granite; the type in fig. 1(G), known as a star jumper, is used on hard stone. The **cup-headed chisel** is used in conjunction with the iron hammer on delicate work such as carving, letter-cutting, etc. It is made in various shapes and sizes: points, chisels and gouges from $\frac{1}{8}$ to 1 in. wide. **Marble tools** are similar in shape and detail to the cup-headed tools but made with hammerheads for use with a light (two-pound) steel hammer.

Mallet-Headed Tools.—These are made for use with the mallet for working on hard stone. They must never be used with a steel hammer, as the mushroom head will snap off. They are made of cast steel, hardened, tempered and sharpened to a knife edge.

The **point**, or **clourer** in Scotland (fig. 1[H]), is sharpened to a narrow cutting edge and is used for taking off, almost to the level required, the rough stone in a series of furrows. The **waster** (fig. 1[I]), has its cutting edge formed into a series of teeth and is used as an alternative to the point. The **claw chisel** (fig. 1[J]), from $1\frac{1}{2}$ to 2 in. wide and formed with teeth, is used for forming drafts on the surface of the stone after roughing down with the point or the punch. The toothed cutting edge prevents the stone plucking or pitting. The **chisel** is made in widths of from $\frac{1}{4}$ to 2 in.; the wider types are known as **boosters**. They are used for forming margins or drafts and for finishing the surface of the stone to a comparatively smooth texture.

A **batting tool**, or **broad tool**, is similar to a booster but is made up to $4\frac{1}{2}$ in. wide. It is for forming a finish known as **batted** on the surface of a stone. This comprises a series of regularly spaced parallel cuts or grooves. The **gouge** is a chisel with a curved cutting edge. Gouges of various sizes and curves are used for working moldings. The **patent claw tool** is similar in shape to a chisel but has a slotted end into which fits a toothed steel cutter. The cutters can be changed and are of various widths up to two inches. It is used for the same purpose as a claw chisel.

Wood-Handled Chisels and Gouges.—These are similar to carpenters' chisels but are stouter at the neck. They are used in conjunction with the dummy for working soft stone and are made in a variety of widths and shapes.

Other Masons' Tools.—**Drags** (fig. 1[K]) are used for producing a finished surface on soft stone. They are made from plate steel varying in thickness from 8 B.G. (Birmingham gauge) for coarse to 18 B.G. for fine and are half elliptical in shape, varying in length up to eight inches and having teeth along the straight edge. They have 4 to 5 teeth per inch for coarse, 8 to 10 for medium and 16 to 20 for fine. They are also made with convex, toothed edges for finishing circular work. **Cocks' combs** (fig. 1[L]) are thin steel plates with finely toothed edges in various shapes and are used for cleaning up the face of molded work on soft stone. **Masons' saws** are used for cutting soft stone and are similar to carpenters' saws but of heavier gauge and with coarser teeth. There are three main types: the crosscut saw, of various lengths for sawing large blocks of stone (worked by two men); the handsaw, available in different sizes, for sawing smaller blocks and ordinarily used by the mason; the whipsaw, a narrow saw of flexible steel from $2\frac{1}{2}$ to 4 ft. long and from 1 to 2 in. wide with a wooden handle at each end in line with the blade that is used for sawing around curves. The **bevel**, or **shiftstock**, consists of a double stock between which is inserted a thin blade that can be set at any desired angle and secured with a thumbscrew. It is used for testing bevels, chamfers, sinkings, etc. The **sinking square** is a tool in which a blade passes through the stock and can

be adjusted. It is used for gauging the depth of sinkings. With the addition of an extra blade the tool becomes a double sinking square. The *mitre square* is made of thin steel plate or hard wood with one edge formed at an angle of 45° and 135° with the long edges. This tool is used for positioning a straightedge at the correct angle for marking out the line of mitres. The *plumb rule* is a wooden straightedge with a pear-shaped hole at one end. A thin cord to which is attached a bob is fixed to the end of the rule so that the bob hangs in the hole. The mason-fixer uses the plumb rule for testing whether the stonework he is fixing is upright.

In addition to the above tools, the mason and the fixer need such items as folding rule, steel squares, steel set-squares, steel wing compasses, scribe, steel straightedges, trowels, rasps, brace and bits, pinch bars and spirit level.

Lifting Appliances.—There are various types of equipment for handling stone, which by virtue of its weight usually has to be lifted by mechanical means. In the ordinary way, cranes of different sorts are used at the quarry and masonry works for moving the large blocks of rough stone. On building sites, the worked stone is unloaded from transport by cranes and hoisted to the various floor levels, but thereafter the individual stones are handled by different forms of light hand tackle. It is necessary to provide attachments to the stone for hooking on to the crane or tackle and these take different forms to suit the size and type of stone to be lifted:

Sling chains are made in varying lengths and capacities. They are mostly used at the quarry or masonry works for lifting large unwrought blocks of stone weighing up to 20 tons or more. At one end is a ring and at the other a hook. The chain is placed around the block, so that it passes through the hook; the ring is attached to the lifting apparatus. If sling chains are used on wrought masonry the clean edges of the stone must be protected with slats of wood to prevent chipping and damage.

Webbing slings are used in the masonry works during the various stages of processing. They comprise two endless solid woven cotton straps attached to shackles which are fitted with rollers to allow the straps to rotate. They prevent damage to edges of stones that are being lifted and they also enable the stone to be turned over while suspended. They are capable of handling loads of up to two tons and range from 10 to 20 ft. in length.

Dogs comprise two steel hooks with rings attached, and are designed so that the greater the weight the tighter they "bite." They are used in conjunction with a chain. A small "dog-hole" is cut at each end of the stone to be lifted to receive the point of the hook. Normally dogs are limited to handle stones weighing not more than six tons.

Lifting pins are single steel pins with rings connected by a chain (fig. 2[A]) which are used for heavy stones. Holes to accommodate the pins are drilled inclined so that the pins cannot pull out. A similar type has the pins connected by a ring and is used on smaller stones.

Three-legged lewis comprises two dovetailed pieces and a centre parallel piece connected together by a shackle and pin (fig. 2[B]). The two dovetailed pieces are first inserted into an undercut mortise in the stone and then the centre piece is placed in position. The shackle and pin are then assembled ready for lifting.

Chain lewis has two curved legs linked by three rings. The

legs are placed into a slightly undercut mortise in the stone (fig. 2[C]). The design is such that the rings tend to pull the top portions of the legs together, thus opening out the bottom portions which bite into the stone. These lewises are only suitable for comparatively light stones.

Split-pin lewises are used for light stones and fit into a single round hole in the stone. The cranked legs, connected by three rings, act on the scissors principle and spread at the bottom, thus gripping the sides of the hole.

STONE-WORKING MACHINERY

Machines play an important part in the conversion of the rough quarry block into finished masonry. They can be classified into the following types: primary saws; secondary saws; molding machines; surfacing machines; lathes; light hand tools (pneumatic or electric).

Primary Saws.—These are used for the initial cutting of blocks into slabs of required thickness. They are of three types: frame saw; large circular saw; and wire saw.

Frame Saw.—This machine has a heavy steel frame which is made to swing or reciprocate horizontally by a power-driven crank via a connecting rod. The frame is suspended on four corner pendulum arms or four slides, which in turn are mounted on four vertical pillars suitably braced for rigidity. The frame, while swinging or reciprocating, can be lowered or raised mechanically on the pillars. Into the frame, thin steel blades are tensioned and positioned to suit the thickness of stone slab to be cut. The blades do not have teeth, the cutting being obtained by abrasion. Sharp sand or steel shot is fed, either by hand or mechanically, on to the blades and sprayed with water, and the action of the blade rubbing on these abrasives forms a thin cut.

Any number of blades can be mounted in the frame, and the speed of cutting can vary between 1 and 12 in. an hour according to the material being cut and the number of blades being used. Blocks measuring up to 12 ft. long, 6 ft. wide and 6 ft. high can be handled by the frame saw.

Large Circular Saw.—There are two types of machines in this category; (1) where the block of stone is made to travel against a revolving circular saw blade; (2) where a revolving circular saw blade is made to travel against a stationary block of stone—this is known as a beam or crosscut saw (see fig. 5). The circular saw blades range from 5 to $11\frac{1}{2}$ ft. in diameter and revolve at a peripheral speed of between 8,000 and 10,000 ft. per minute.

The cutting agent is industrial diamonds and these are used in two forms: either single diamonds of about one-half carat each, or crushed diamonds. The single diamonds are welded into steel sockets, which are in turn fixed around the periphery of the saw blade about $1\frac{1}{2}$ in. apart. The diamonds are set in different positions in the steel sockets and the sockets fixed in the saw blade in a sequence that will give a coverage of diamond cutting points over the width of the blade.

Crushed diamond, in various grades, is sintered into a metal bond and formed into segments. These segments are fixed around the periphery of the saw blade at regular intervals. As the segments are impregnated with crushed diamonds they cut over their full width and do not have to be set in sequence as with the single diamond type of socket. High-pressure water is fed on to the blade to wash away the stone dust and to keep the blade cool.

These large circular sawing machines are capable of very fast cutting on most hard and soft stones, but they are not suitable for sawing granite, the primary sawing of which is usually done on the frame saw or the wire saw.

Wire Saw.—This comprises a long length of stranded steel wire traveling over pulleys so that a length of the wire is free to rub on the top of a block of stone. An abrasive, mixed with water, is fed automatically on to the wire at the point of contact with the stone and the pulleys over which the wire travels are mechanically lowered very slowly, so that a cut is gradually formed.

Secondary Saws.—These are used for cutting the slabs from the primary saws to the required sizes; for cutting the joints of stones which have been worked on the molding machines; for cutting notches and checks and for all other smaller sawing operations.

FIG. 2.—THREE TYPES OF LIFTING APPLIANCES: (A) LIFTING PINS; (B) THREE-LEGGED LEWIS; AND (C) CHAIN LEWIS

These machines are all of the circular-saw-blade type and have movable tables, either hand- or power-operated, for traversing the stone against the saw blade, or alternatively they can be smaller versions of the beam or crosscut machines described under primary saws. The cutting agent on the saw blade can be either silicon carbide (carborundum) in a continuous rim or crushed diamond segments.

Molding Machines.—As their name implies these machines are used for forming molded or profiled surfaces such as cornices, string courses, etc. A power-driven table, on slides, moves the slab of stone against cutting tools mounted in a toolbox on a cross-head. The toolbox is adjustable vertically and horizontally. After "roughing out," steel plates shaped to the profile required are mounted in the toolbox to form the correct contour on the stone. The cutting tools are usually tipped with tungsten carbide to give a better and longer-lasting performance. These machines are used on all soft and hard stones, but not on granite. Molded work on granite is invariably done by hand.

Another type of molding machine works on the same principle as the secondary saw, but instead of a saw blade a wide carborundum drum is fitted. This drum can be formed to the required profile and, when rotated at high speed, grinds the stone to shape.

Surfacing Machines.—These are used for producing different surface finishes on plain face stonework. There are three main types: rubbing table; jenny lind; and dunter.

Rubbing Table.—This comprises a large cast-iron circular disk, up to ten feet in diameter, which is power-rotated on a vertical axis. Water and sharp sand are fed on to the table and the stone is placed face downward against a stop so that the action of the rotating disk with the sand and water rubs a smooth face on the stone. It is used on granite and marble as well as hard stone.

Jenny Lind.—This machine is used for rubbing and polishing stone, marble and granite. It consists of a head which is power-rotated on a vertical axis and to which circular disks, fitted with different forms of abrasive, can be attached. The head is mounted on a double hinged arm which allows it to be moved freely over a horizontal surface on the pantograph principle.

Dunter.—A machine used on granite for working large surfaces roughly level and straight. It comprises an arm, capable of moving over the surface of the stone, to which is fixed a percussion tool actuated by compressed air.

Lathes.—These are similar to machinists' and wood-turning lathes, but are more sturdily constructed. Stone columns are turned with the aid of a toolbox mounted on a saddle as in metal turning, but stone balusters are normally turned with hand tools using a tool rest as with wood turning.

Light Hand Tools.—Power-operated hand tools are widely employed in masonry production. Chipping hammers are extensively used by masons on hard stone, marble and granite and speed up their work. High-speed rotating heads are used for rubbing and polishing, and pneumatic and electric percussion and rotary drills are used for forming holes in all types of stone.

PRODUCTION AND FIXING

Before stonework for a building can be produced and fixed, much planning by the masonry contractor is necessary. A time program must be worked out to fit in with all other trades, availability of labour determined, supplies of raw stone from the specified quarry secured, drawings made and approved, and transport and plant for fixing arranged. The usual routine is for the masonry draftsman or setter-out, as he is called, to prepare working drawings, normally to a scale of $\frac{1}{2}$ in. to 1 ft., from details supplied by the architect. Where the building has a steel or reinforced concrete frame, details of this would be required from the consulting engineer so that details can be worked out for attaching the stones to the frame. These working drawings also have to be furnished to other specialist firms such as window-frame suppliers, etc.

It is important to ensure that the design of the stone jointing allows for proper bonding, *i.e.*, that a proportion of the individual stones are of sufficient depth, front to back, to get support from, and be built into, the brick or concrete backing to the stonework. (This condition would not apply to solid masonry walls, but such

construction is now rarely used.) Where it is not possible to provide bonding, metal ties and supports must be used. (See *Metal Ties and Supports*, below.)

It is also important with the majority of stones, and particularly with stratified stones, that they are worked and fixed on their natural bed; *i.e.*, with their laminae horizontal. Doing so ensures greatest strength and durability. There are exceptions to this rule: in arch stones the natural bed should be at right angles to the face and parallel to the centre line of the voussoirs; in cornices with large projection, the natural bed should be vertical and at right angles to the face, except for corner stones, which should be fixed on the natural bed.

When all details have been verified, each individual stone in the building is given an identification number on the working drawing, the necessary templates are cut out of sheet zinc and a schedule, giving a full description of each stone, is issued to the foreman, who then marks out the raw stone as economically as possible. The stones are sawn and passed through the various processes, and on completion the identification number is cut into each stone and the stone is stacked in proper sequence ready for delivery to the building.

Fixing.—The mason-fixer is responsible for setting the stones on the building in their correct order and position. He is issued a copy of the working drawings on which all relevant information is given and calls for delivery of stone from the masonry works in the required sequence.

Stones are set into position with the aid of light lifting appliances, usually of the endless-chain tackle variety, and must be perfectly level and upright. For setting arch, lintel and similar stones, wooden supports known as centres have to be provided as a support for the stones until the mortar in the joints has set and the stones are capable of supporting themselves. The centres are then removed.

Stones are never fixed directly in contact with each other; they always have a mortar joint separating them. This joint can vary from $\frac{1}{8}$ to $\frac{1}{4}$ in. wide according to the architect's design and the type of stone. In addition to this mortar joint, the vertical joints of the stones have a V-shaped groove cut into them, called a joggle, so that when two stones are fixed the grooves correspond. Cement grout is poured into the joggle to lock the stones together.

When an area of stonework has been fixed, it is usual to protect the exposed face from damage and dirt until such time as the whole building is completed. This protection is given by brushing on a thick coating of slurry composed of stone dust and lime mixed with water. (This treatment does not apply to granite, marble and certain soft stones.) On completion of the building, this protective coating is washed off and the exposed face of the stonework rubbed down either by hand using abrasive blocks such as sharp grit stone or carborundum, or by mechanical spinners—high-speed rotating heads with flexible abrasive pads.

The scaffolding, from which the mason-fixer works, has to be designed as an independent structure; it must have no fixings into the wall of the building as in the case of scaffolding for brickwork. It is known as a mason's independent scaffold.

FIG. 3.—METAL TIES AND SUPPORTS USED IN PRODUCTION AND FIXING: (A) CRAMPS FOR FIXING STONE TO CONCRETE; (B) CRAMPS FOR FIXING STONE TO BRICKWORK; AND (C) GENERAL-PURPOSE STANDARD CRAMP

FIG. 4.—ARCHITECTURAL TERMS ILLUSTRATED IN ELEVATION, SECTION AND PLAN

Metal Ties and Supports.—In modern building construction it is very frequently necessary to use metal ties and supports for securing the stonework to the structure. The design of these has to be worked out to suit individual cases, but there are certain stock designs which have wide application (see fig. 3).

In all cases, metal fixings should be made of nonferrous metal or, if made of iron or steel, should be galvanized, sheridized or in some other way treated against rust and corrosion. Rusting iron fixings are the cause of much damage to stonework in many older buildings. Cramps and dowels are used for anchoring together stone copings, cornices, mullions and similar items. Slate is sometimes used for these purposes.

Mortars.—The mortars used for masonry vary according to the kind of stone and the structural requirements.

Wrought stonework, by virtue of the bonding arrangements of the stones and the large true joint surfaces, does not depend on the mortar for strength and, generally, the mortar when set should be no harder than the stone.

For most hard and soft stones, the mortar should be a mixture of crushed stone, hydrated lime and cement. Washed sand can be used in place of crushed stone. For granite the mortar is usually a mixture of washed sand and cement, while for marble, plaster of paris is normally used. Pointing in the masonry joints should be done with the same mortar and at the same time as fixing. For filling joggles, neat cement is normally used.

TECHNICAL TERMS, SURFACE FINISHES AND TYPES OF STONE

Technical Terms.—The following are some of the terms used in masonry and not explained in the article (see fig. 4).

Apex stone is the top stone of a gable, spire or pediment.

Arch is a method of spanning an opening with masonry consisting of a series of wedge-shaped stones, known as voussoirs or arch stones, which are supported by lateral pressure induced across the radial joints. The three types are: *flat arch*, in which the voussoirs are arranged to provide a horizontal soffit; *joggled arch*, in which adjacent stones are interlocked by means of rebates or tongues and grooves; and *skew arch*, whose face is not at right angles to its supports.

Arris is the line or edge made by the junction of two surfaces, forming an external angle.

Baluster is a short pillar, usually circular on plan, the characteristic feature of which is the bulging-out or swell of the lower part.

Band course is a plain course of stone continued horizontally along the face of a building.

Banker is a mason's workbench, made of heavy timber or blocks of stone.

Barge is a projecting stone drip at the base of a chimney stack to throw off water.

Batter is an inward inclination of the exterior face of a wall.

Bed is the lower or upper surface of a block of stone. The term *natural bed* is used to indicate the way sedimentary rocks were originally laid down or deposited. Also, a bed is the line of cleavage between the laminae of stratified rocks.

Bed mold is the lowest molded member of a cornice.

Birdsmouth is a notch cut on the edge of one piece of stone to receive the square edge of another.

Blocking course is a plain course of masonry over a cornice.

Bonder is a stone whose longer dimension is in the thickness of the wall.

Cladding consists of thin slabs of stone used externally as a nonload-bearing covering to the structure of a building.

Closer is a stone placed in a course of masonry to fill or close a gap.

Column is a free-standing vertical member usually circular on plan.

Coping, or capping, is the topmost course of masonry on a wall usually made wider than and arranged to overlap the wall and having a sloping top to throw off rainwater.

Corbel is a stone or series of stones which projects from a wall, often used as a bracket or support.

Cusp is the projection from the inner face of the curves of Gothic arches.

Damp-proof course is a layer of impervious material interposed in the bed joint of a wall to prevent the passage of moisture.

Dentil is a series of small rectangular blocks cut in the bed molding of cornices, giving the appearance of a row of teeth.

Dressing is a general term used for all wrought masonry.

Entasis is the outward curvature of the shaft of a column to counter an illusionary concave appearance.

Finial is a finishing ornament at the top of a gable, a pediment or pinnacle.

Gable is a small gable-shaped carved panel, frequently used in Gothic stonework for apex stones and in spires, etc.

Galleting, small pebbles or chips of flint pressed into the mortar, while still soft, in the joints of rubble or flint walling.

Gargoyle is a projecting stone formed as a waterspout for throwing rainwater from gutters clear of the walls. In early work it was often carved into grotesque shapes of animals and other forms.

Hoodmold, or dripstone or label, is a projecting molding or canopy over a door or window opening to throw off rain from the walls of the building.

Impost is the top member of a pier or pillar from which an arch springs.

Jambstone is one of a number of stones forming part of the vertical surface at the sides of a door or window opening.

Joggle consists of adjacent recesses in vertical joints of stones for filling with cement grout, and is also a projection on one stone which fits into a corresponding recess in another stone.

Keystone is the central stone of an arch.

Kneeler is a stone bonded into the wall and forming an intermediate length of the coping to a gable wall.

Linings are thin slabs of stone, marble or granite used internally as a nonload-bearing covering.

BY COURTESY OF THE ANDERSON-GRICE CO., LTD.

FIG. 5.—CIRCULAR CROSSCUT SAW FOR STONE

Lintel is a stone which spans in one piece the top of an aperture.

Mason's mitre is a mitre worked out of a single piece of stone and not forming a joint at the mitred angle as in a joiner's mitre.

Modillion is an ornament bracket worked out of the solid at regular intervals in the molded member under the corona of a cornice.

Morice is a sinking in a stone to receive a corresponding projection on another stone, or to receive a dowel, cramp, rail, lug, etc.

Mullion is a vertical member subdividing a window.

Padstone, or template, is a stone incorporated in the structure to distribute a concentrated load.

Perpend is a through bondstone faced on both sides.

Perpend is a vertical joint in masonry.

Pier is any load-bearing vertical mass of masonry, either detached from or attached to a wall.

Pilaster is a flat rectangular pillar which slightly projects from a wall.

Plinth is the projecting base of a wall or column.

Quoin is a stone at an external angle of a wall.

Rebate is a continuous rectangular sinking along the edge of a stone to receive window or door frames or other similar members.

Respond is a half pillar or pilaster corresponding to another or to a pillar opposite to it.

Returned end is the termination of a stone worked to match the face with an external mitre.

Reveal is that part of the jamb of a window or door opening which is not covered by a frame.

Sill is the lower horizontal member of a window opening and certain external door openings.

Skewback is an inclined or splayed surface of an abutment from which an arch springs.

Soffit is the undersurface of a lintel or arch, or the lower surface of a vault.

Spandril, or spandrel, is a triangular space enclosed, approximately, by the curve of an arch with a horizontal line drawn through its apex and a vertical line drawn through its springing.

Springer is the stone from which an arch springs.

Springing line is the level from which an arch commences.

Stool is a seating such as that on both ends of a sill on which a jambstone is fixed.

Stopped end is the termination of a molding worked in the solid.

String course is a narrow molded or plain projecting course of stone continued horizontally along the face of a building.

Throat is a groove worked in the undersurface of overhanging stonework to prevent rainwater flowing back to the wall.

Transom is a horizontal member subdividing a window or other opening.

Vousoir is a wedge-shaped stone forming a unit of an arch.

Walling: ashlar is masonry consisting of plain blocks of stone, finely dressed to given dimensions and laid in courses; **block in course** is roughly squared blocks of stone which may vary in length, having worked beds and hammer-dressed faces and joints and set in courses which may vary in height not exceeding 12 in. (used in heavy engineering masonry); **brought to courses** is walling, similar to uncoursed rubble, which is roughly leveled up to courses at intervals usually to correspond with the heights of the quoin and jambstones; **coursed rubble** is roughly squared stone walling to courses to suit the heights of corner stones; **dry walling** is walling without mortar; **polygonal (rag walling)** is walling built of stones of irregular shape which may be roughly worked to fit adjacent stones; **sneaked** means a rubble wall in which the stones are squared but of irregular size, with small stones, known as "snecks," introduced to break the line of the courses.

Weathering is working the top face of a stone to an inclined plane for the purpose of throwing off rainwater.

Surface Finishes.—There is a wide range of different finishes used in masonry; the following are the more common.

Axed is used for granite only, having a surface obtained by using an axe or a patent axe. "Fine-axed" is when the surface has been chopped with fine-axe marks. "Once-axed" is the term used when the surface has been roughly chopped with an axe.

Batted means having a surface comprising a series of parallel grooves formed with a wide batting tool regularly spaced across the face of the stone. The number of grooves may vary from five to ten per inch.

Boasted means a stone finished by dressing with a boaster.

Boasted for carving refers to a stone roughly worked to the approximate form required by the carver or sculptor.

Combed means having all irregularities on the exposed surfaces of soft stones worked off by the use of a drag or comb.

Dabbled means fine and close sparrow-pecked with a sharp point.

Drilled means having a surface worked with a drill, leaving a rough beveled edge as left by a dressing knife or guillotine, as opposed to a sawn edge, which is not beveled.

Eggshell means having a dull polish or a matte surface.

Face-bedded is a stone cut so that the natural bed is vertical to and parallel with the face.

Fluted means having a surface worked into a regular series of concave grooves.

Hammer-dressed (for granite) means having a rough face prepared with a hammer.

Joint-bedded is a stone cut so that the natural bed is vertical to and parallel with the joints.

Pencil-arressed means having the arris rounded to a radius of approximately 1 in.

Picked, or pecked, is a dressing obtained by means of a point tool or pick.

Pitched is a surface produced by a pitching tool so as to resemble the natural rock face.

Polished means having a high-gloss mirrorlike finish.

Punched is a finish obtained by removing the larger irregularities by means of a point tool.

Reredd is a surface worked into a regular series of convex ridges.

Reticulated means an irregular network of bands worked on a true-faced stone, the sinking between the bands being about 1/2 in. deep, worked true to a gauge and "picked" with a fine point.

Rock-faced is the natural face of the rock or a dressing resembling it (see also "Pitched").

Rubbed is a finish obtained by rubbing the surface with abrasives to the degree of smoothness required.

Rusticated refers to a stone which has a sunken, dressed margin.

FIG. 6.—MASONS CARVING GOTHIC TRACERY HEAD

Shotted is the face which results from grinding with steel shot by means of a heavy steel ring used in a polishing machine.

Tooled is a surface showing the mason's tool marks.

Vermiculated is a surface which has a dressing taking the form of irregularly shaped sinkings resulting in winding wormlike ridges.

Types of Stone.—There are five main classifications of natural stone used in masonry. They are: *granite*, a holocrystalline plutonic rock composed of quartz, feldspar, mica, or hornblende and accessories; *marble*, a granular limestone, recrystallized by heat or pressure; *slate*, a rock derived from argillaceous sediments or fine-grained volcanic ashes by metamorphism and characterized by a cleavage along planes independent of the original bedding; *limestone*, a bedded rock consisting essentially of calcium carbonate; *sandstone*, a bedded rock composed of grains of quartz sand naturally cemented together.

The use of the different types of stone depends largely upon the geographical situation of the source of supply, transport facilities, availability of skilled labour and costs. Granite is the hardest and most durable of all the building stones and is widely used for architectural, civil and marine engineering and decorative purposes. It comes in a wide range of colours and textures and is generally capable of being polished. Marble is used mainly for internal wall linings, staircases, floors and decorative work. It is also used externally, mostly in thin cladding to walls and, where supplies are abundant such as in Italy, as solid masonry. There are endless varieties and combinations of colours, which are considerably enhanced when the material is polished. Slate is used extensively as a roofing material and also for floors, stair treads, shelves and decorative work. In the second half of the 20th century, it has found favour as an external cladding material in some modern buildings. This particularly applies to the green variety of slate, which is used as panels in conjunction with other stone dressings. Limestone and sandstone are the most widely used stones for general masonry work. There is a considerable variety of colour, texture and quality, and special care is needed in selecting the type to be used to ensure that it will withstand the climatic conditions prevailing in the locality of the building. See **BRICKWORK**; see also references under "Masonry" in the Index.

MASORETES (MASSORETES) were the keepers of a cumulative body of biblical text tradition (Masorah), which they codified in order to ensure the accurate transmission of a standard Hebrew Bible text. They flourished at the Babylonian and Palestinian academies of Jewish learning between the 7th and the 10th centuries A.D. and are chiefly responsible for the text tradition of the Hebrew Bible, as found in all the manuscripts known before 1947 (when ancient biblical manuscripts were found in the Dead sea region). It appears in all printed editions and has come to be known as the Masoretic text (MT).

Historically, the text of the Hebrew Bible is made up of three distinct components. In order of antiquity and stability they are: the basic consonants; the vowel letters; and the system of Maso-

retic marks for vowels, accents and cantillation. In the beginning there was a consonantal text in pre-exilic Hebrew script with or without word dividers and with only a sprinkling of *matres lectionis*; i.e., the letters *waw*, *yod* and *he* indicating long *u*, *i* and *o*. The ancient Greek version of the Pentateuch (3rd century B.C.) was translated from just such a sparsely vocalized Hebrew text.

As the study and recitation of Scripture spread to schools and local synagogues, more vowel letters were introduced as an aid in reading. Some of the biblical manuscripts from the caves of Qumran near the Dead sea, besides displaying differences in wording, also show excessive use of vowel letters. To hold deviations under control, three standard scrolls (according to rabbinic sources) were exhibited in the Temple forecourt in Jerusalem, and "correctors" were maintained out of the public treasury, so that copies could be compared and divergencies in wording and spelling checked. After the fall of Jerusalem (A.D. 70) the "hedge" around the Hebrew Scriptures was complete. Biblical manuscript fragments from the caves of Wadi Murabba'at (south of Qumran) dated between A.D. 70 and 135, in contrast to the earlier Qumran manuscripts, are already in accord with our printed Hebrew Bible.

The transmission of the text continued uninterruptedly, though only fragments have come down from before the 10th century. Origen and Jerome as well as rabbinic literature bear witness to the stability of the text. This does not mean, however, that the Hebrew Scriptures were free from earlier textual corruptions or immune to new scribal errors. Although tradition scrupulously supervised the copyists' work, errors which had earlier been admitted into the text were perpetuated. The Masoretes of the 8th century were probably stimulated by the challenge of Karaism (q.v.), which, by contesting the authority of the rabbis, revived intensive Bible study. They devised safeguards to prevent misspellings, recording variant readings meticulously and providing the text with fixed vowel signs and accents.

About the 8th century A.D., coinciding with a similar development in Syriac and Arabic, three systems of Hebrew vocalization emerged out of a few rudimentary diacritical marks. In Babylonia, where the eastern Masoretes were active, six vowel sounds, stressed and unstressed, plus a *sheva mobile* were represented by a combination of tiny letter marks and dots all placed above and between the consonants. Of the two Palestinian systems, the Tiberian has 13 vowel signs made up of dots and dashes beneath the line and denoting largely the quality of each vowel. The Masoretes also constructed a graphic scheme for accents serving both as musical notes for cantillation and as guides for proper sentence division. There are disjunctive accents (or "masters") indicating various degrees of stress and pause, and conjunctive signs ("servants") marking continuity.

A critical index to the biblical text also was compiled. All inconsistent spellings, alternative readings (*qere* and *kethib*) and any other peculiarities in the text were noted, registered and counted. These abbreviated notations were inserted in the upper, lower and side margins of the text (marginal Masorah); at the end of the manuscript (final Masorah) all data, including even the total number of letters in each book, were arranged in alphabetic order of content.

Toward the end of the 9th century, the western or Palestinian school achieved dominance, continuing in two main families of Masoretes, Ben Naphtali and Ben Asher of Tiberias. Their fully vocalized and annotated manuscripts, with accompanying manuals, became models for all copyists. Differences in the work of the two schools, involving minutiae of vocalization, can hardly be gauged by modern scholars, since Aaron ben Asher's manuscript was later accepted by Maimonides and replaced rival copies.

When the text of the Hebrew Bible was prepared for a second printing by D. Bomberg at Venice in 1524–25, the editor, Jacob ben Hayim, found it difficult to secure reliable Masoretic manuals. Older manuscripts prepared by the great masters were not available to him. In the 19th century the basic Masoretic works were again re-examined and critically evaluated. A methodical search for old manuscripts in the Cairo Geniza and elsewhere brought important results. In 1937 the third edition of R. Kittel's *Biblia Hebraica* was based on an original copy belonging to the Ben Asher

tradition and dated A.D. 1008 (Leningrad Public library, catalogued as B 19a). Part of the Aleppo codex, the most authentic Masoretic manuscript, vocalized and annotated in A.D. 930 by Aaron ben Moses of the Ben Asher family and salvaged at mid-20th century, constitutes the basis of the Jerusalem edition under preparation by the Hebrew University Bible project. (S. I.)

MASPERO, GASTON CAMILLE CHARLES (1846-1916), French Egyptologist and one of the most brilliant scholars and administrators of his generation, was born in Paris on June 23, 1846, his parents being of Lombard origin. He was educated at the École Normale and in 1869 became teacher (*répétiteur*) of Egyptian language at the École des Hautes Études. In 1874 he was appointed professor at the Collège de France.

In Nov. 1880 Maspero set out for Egypt as head of an official archaeological mission, which developed into the Institut Français de l'Archéologie Orientale. The following year, on the death of A. F. E. Mariette (*q.v.*), he became director-general of excavations and of the antiquities of Egypt, a post that he held until June 1886. During these years he organized the mission which was mainly occupied in recording the scenes and inscriptions in many important tombs, particularly those in the Valley of Kings at Thebes, and continued Mariette's work at the Bulaq museum and the excavations of the pyramids at Saqqarah. Early in 1881 Maspero suspected the clandestine discovery of a royal tomb and instituted the investigations that led to the opening of the tomb at Hawd ad Dayr al Bahri the following July. The results of Maspero's intensive study of the royal mummies and other contents of the tomb were published in 1889. During 1886-89 he resumed his professional duties in Paris, afterward returning to Egypt to take up his former post. One of his principal tasks was the arranging and cataloguing of the now vast collection from Bulaq, which had just been transferred to the Cairo Museum of Antiquities at Qasr an-Nil. Maspero also regulated excavations throughout the country and attempted to prevent illicit trading in antiquities. He was much concerned with the preservation and strengthening of monuments; his repairs and clearance of the temple at Karnak led to remarkable discoveries in later years (see THEBES). It was also under Maspero's direction that G. A. Reisner carried out the archaeological survey of Nubia (1907-09).

Maspero was created knight commander of the Order of St. Michael and St. George by Edward VII in 1909. In 1914 ill-health compelled him to return to France, and he died suddenly in Paris on June 30, 1916.

Among his best-known publications are *Histoire ancienne des peuples de l'Orient* (1875), which outlines the history of the near east before Alexander, and an expanded and more detailed study of the same subject, *Histoire ancienne des peuples de l'Orient classique*, three volumes (1895-97); *Études de mythologie et d'archéologie égyptiennes*, eight volumes (1893-1916); *L'Archéologie égyptienne* (1887; several times translated into English); *Les Inscriptions des pyramides de Sakkarah* (1894); *Les Momies royales de Deir el-Bahari* (1889); *Les Contes populaires de l'Égypte ancienne*, 4th ed. (1914; English ed. 1915); *Causeries d'Égypte* (1907; translated by Elizabeth Lee as *New Light on Ancient Egypt*, 1908).

(W. R. D.)

MASQAT: see MUSCAT AND OMAN.

MASQUE, a band of masked persons of the same sex who, accompanied by torchbearers, arrived at a social gathering to dance with the guests. It could either be a procession introduced by a

presenter or an elaborately staged show in which a brief lyrical drama heralded the appearance of masquers who, having descended from their pageant to perform figured dances, reveled with the audience until summoned back into their pageant by farewell speech and song. The masque theme was usually mythological and symbolic and complimentary to the noble or royal host. The dramatic business was performed by professionals, the masquers remaining mute until they consorted with the guests. Traditional festivals and social events were celebrated by masques and the Twelfth Night court masque was so diplomatically important that foreign ambassadors intrigued for positions in the auditorium.

Origin and etymology are obscure. The masquerade, a popular carnival amusement akin to mumming (see MUMMERS), was transformed by Lorenzo de' Medici into a performance designed to illustrate a theme and accompanied by songs explaining the meaning of costume and pageantry. By the time it reached France it had become very spectacular and toward the end of the 16th century provided material for the French and Italian humanists who, attempting to revive classical drama, invented opera and ballet de cour. The English court masque was continuously influenced by its continental analogues.

In 15th-century Ferrara, young men in masks and dominoes paraded the streets at carnival time and penetrated uninvited into festive gatherings. The fashion reached France in the 16th century. Henry VIII introduced it into England on Twelfth Night 1512, when he and 11 others, disguised in masks and Italian dominoes, entered the banquet hall and invited ladies to dance and converse. Some refused, scared possibly by the rumoured licentiousness of continental masquers. Dominoes were soon discarded and the masque, combining with other kinds of entertainment, became increasingly dramatic. The earliest extant example of a developed masque, *Proteus and the Adamantine Rock*, presented by gentlemen of Gray's Inn, London, in 1594, complimented Elizabeth as empress of hearts and of the ocean.

The production of *Of Blacknesse* in 1605 marked the beginning of the partnership of Ben Jonson and Inigo Jones and the introduction of Italian methods of staging. Instead of dispersed decorations, a scene in perspective was presented on a raised stage. Later, Jones introduced methods of instantaneous scene-changing. In 1609, the *Masque of Queenes* opened with an antimasque of witches who symbolized evil and vanished at the appearance of the virtuous masquers. Jonson used the antimasque as foil to the main masque; but it gradually ceased to be functional and became a series of entries of grotesque or realistic types with little relevance to the central theme. The sacrifice of poetic unity to variety and spectacle led to a quarrel between Jones and Jonson and after 1631 the libretti were composed by more subservient poets. The term "masque" was sometimes used sufficiently loosely to include entertainments such as Milton's *Comus*.

The performance of *Salmacida Spolia* in 1640 closes the history of the court masque, which was too intimately bound up with social life to survive the fall of the monarchy.

(E. E. H. W.)

MASS (Lat. *missa*) is the common designation for the service of the Eucharist when it is celebrated with Roman ritual and in the Latin language, as by the vast majority of Roman Catholics. The name, which is comparatively late, derives from the dismissal formula *Ite, missa est* ("Go, it is the dismissal"). The word has been naturalized in most European languages (French *messe*, German *Messe*, Italian *missa*, Spanish *missa*).

This article deals first with the external forms of the Latin

Mass rite, as it is known to the vast majority of Roman Catholics, and briefly with their history; the second part of the article is concerned with the musical settings of the Mass. For the book containing the prayers and instructions for the Mass, *see* MISSAL; for the theology of the Mass, *see* EUCHARIST; for the history of the Mass and other matters related to it, for other Latin rites, and for the eucharistic rite among Eastern Christians and among Protestants, *see* LITURGY.

THE RITE OF THE MASS

The Latin Mass is a union of two services distinct in origin. The first, or Foremass, is an adaptation of the Jewish Sabbath synagogue service (*see* LITURGY, JEWISH) and consists of recitations from both Old and New Testaments interspersed with set invocations and prayers. It is often called the Mass of the Catechumens because at its close (marked on Sundays by the sermon) in early days unbaptized persons under instruction in the Christian mysteries used to be dismissed from the assembly. The second service (which when there is no sermon follows immediately on the first) is the commemoration of the Last Supper by the reenactment of Christ's blessing of bread and wine with thanksgiving and partaking. It is called the Mass of the Faithful, because to it only the baptized were at first admitted. The two services have been united in all localities since the 3rd century. St. Justin Martyr as early as the 2nd century was able to describe the oldest, simplest Mass of the city of Rome as consisting first of readings from an apostolic letter, Gospel and sermon; followed by the kiss of peace, offering of bread and wine, eucharistic prayer and communion.

By the time the two parts had been fused, the Eucharist was already a purely sacramental rite. At first, the sacrament was given during a meal; the Last Supper itself was probably the Passover, and the subsequent meals may have been friendly *haburah* suppers. Paul (I Cor. xi, 20-34) and Luke (xxii, 7-20) set their accounts of the Eucharist in the framework of a meal, although Matthew and Mark mention no meal other than consecrated bread and wine. (A vestige of the meal celebration was the giving of milk and honey with symbolic meaning between the two communions in the baptismal Mass of Hippolytus' *Apostolic Tradition*.)

The Mass of the Catechumens.—This consists of the following parts:

1. An introductory psalm and form of confession, recited at the foot of the altar steps. This, originally the priest's private preparation for Mass, was added on to the beginning of the service in the 16th century.

2. A few verses, usually from a psalm, read at the altar and called the introit (Latin *introire*, "to enter"). It was introduced about the 5th century and was originally a fairly long psalm-chant, marking the formal beginning of the Mass.

3. A ninefold invocation of Christ (in Greek), beginning *Kyrie eleison* ("Lord, have mercy"; *see* KYRIE), which originated in its present form from the east in the 5th century. It is the remnant of a former litany with procession.

4. An eastern hymn, *Gloria in excelsis Deo* ("Glory to God in the highest").

5. A scriptural salutation to the people, *Dominus vobiscum* ("The Lord be with you").

6. One or more prayers (collects) presenting to God the petitions of the assembly.

7. A single lesson from the Old or New Testament. The Jewish synagogue service had several lessons with a prayer after each; certain Masses during penitential seasons perpetuate this arrangement.

8. A few verses, usually from a psalm, with recitation of alleluia (or, on certain occasions, singing of the tract, a penitential chant). This is called the gradual (*q.v.*), from Latin *gradus*, "step," because at an early period it was sung from the steps of the altar (a whole psalm being then customary).

On certain days a sequence (a kind of hymn) is sung between the gradual and the Gospel: the *Victimæ paschali* at Easter, the *Veni, sancte Spiritus* at Whitsun, the *Lauda Sion* at Corpus Christi, the *Dies Irae* at All Souls' and certain requiem Masses and the

Stabat Mater on the Feast of the Seven Sorrows.

9. A portion from one of the Gospels, which marks the culmination of the Mass of the Catechumens. At all Masses the people stand for the reading; at solemn ones the deacon chants it from a place set apart in the sanctuary; acolytes with lighted candles attend the book and the deacon incenses it and kisses it. These and similar rites have developed to mark the honour in which the book of Christ is held. On Sundays a sermon follows, on the theme of the Gospel.

10. On Sundays and great feasts the Nicene Creed (*see* CREED) is then recited, a custom dating from the 5th century in the east but later in the west.

The Mass of the Faithful.—Now begins the eucharistic rite proper. Its four parts are:

1. Offering of materials for sacrifice (offertory).

2. Thanksgiving—commemoration—consecration (eucharistic prayer or canon, called in the east *anaphora*).

3. Breaking of bread.

4. Communion.

Offertory.—This was at first preceded by a series of solemn collective prayers, which survive only in the unique liturgy of Good Friday; the last vestige of them in the normal Mass is the *Dominus vobiscum* and *Oremus* ("Let us pray"). Thereupon a verse is recited, which was once a whole psalm or canticle. During this the people used to carry gifts to the altar, from which the priest would select bread and wine for the sacrifice. But now the bread is prepared in advance in the form (since the early middle ages) of flat, unleavened, circular wafers, a large one for the priest and small ones for the people, in place of the earlier loaf. These wafers are called Hosts (Latin *hostia*, "victim"). All that remains of the gift procession is the presentation of wine and water for the chalice by a server. The mingling of drops of water with the wine is mentioned in the 2nd and 3rd centuries and symbolizes the union of the people with Christ. The priest holds up in a gesture of offering first the Host (on a flat metal plate, the paten) and then the chalice, at the same time reciting silently prayers to implore the salvation of the world through the "spotless victim" and the "chalice of salvation." These prayers are ancient but were not adapted to this context until about the 10th-11th centuries. Then, still silently, the priest recites a psalm while water is poured over his fingers by the server in symbol of the purity needed to offer the sacrifice worthily. In early days the priest had to wash his hands thoroughly after handling the people's gifts. Next he invites the people to pray that their sacrifice and his may be acceptable to the Almighty and recites the secret, a silent prayer asking God to accept the gifts. This is the only primitive offering prayer and varies according to the day. It is followed by the preface, or prayer before the people, introduced by exhortations to them to lift up their hearts and give thanks. Primatively, the preface marked the beginning of the canon, but it is now separated from it by a triple *Sanctus* ("Holy, holy, holy") with the *Benedictus* and *hosanna* acclamation (Matt. xxi, 9), which came to be interpolated here from another position.

Canon.—The three parts of the primitive canon were: (1) thanksgiving (commemoration of the supper, consecration of the bread and wine, memory of the passion, death, resurrection and ascension of Jesus Christ); (2) oblation of the gifts; (3) calling down of the Holy Spirit or *epiclesis* (only in eastern liturgies). By the 4th century the unity of these parts was broken through the introduction of the several prayers additional to the *Sanctus* which are said today; for many hundreds of years the canon has been recited silently throughout. Before the consecration comes first a prayer presenting the offerings; second, a prayer for the living (which originally involved the reading of the diptychs or lists of people to be prayed for; *see* DYPYCH), followed by a commemoration of many saints; third, a recalling of the purpose for which the Mass is offered; and fourth, an appeal for the acceptance of the sacrifice. After the consecration is recited the memorial of the saving events at the end of Jesus' life, which is called the *anamnesis* and is fused with the prayer of oblation. Next comes a prayer that God will accept our sacrifice as he accepted those of old, followed by a prayer for those shortly to communicate. After

this comes a prayer for the faithful departed, whose names were formerly read from the diptychs, and a second list of saints. The priest, lifting up the large host and the chalice in a last gesture of offering, ends the canon with a solemn doxology whose last words are uttered aloud and to which the people answer "Amen." This is historically and liturgically important, for by it the people signify the offering of themselves with the gifts.

Breaking of Bread.—This and the communion originally followed straight upon the canon, but the recitation of the Lord's Prayer (*q.v.*) or Our Father (*Pater Noster*) was early transferred from after the communion to before the breaking of bread. The last petition, "Deliver us from evil" (*libera nos a malo*), has from the earliest times been followed by an expansion (embolism) of its theme; at the close of which the breaking of bread (fraction) takes place. This, since the introduction of separate Hosts for the people's communion, has become a purely ritual breaking of the priest's Host, accompanied by a peace greeting. He breaks off a further small piece which he places in the chalice. There follows a brief prayer with the theme of this ritual union of the body and blood of Christ as a sign of resurrection. The commingling also recalls the ancient, long-obsolete custom of the pope sending a piece of consecrated bread from his Mass to all Roman churches as a sign of unity. The kiss of peace, now a preparation for communion, follows, having, in the west, been transferred here from the offertory. It now takes place only at High Mass and is there confined to the clergy. It is preceded by a threefold invocation of the Lamb of God (*Agnus Dei*) and by a medieval prayer for peace and unity; and followed by two medieval antecomunion prayers.

Communion.—Before receiving communion, the priest makes a scriptural invocation and prays that the body and blood of Christ may preserve his soul to life everlasting. After receiving under the forms of both bread and wine, he then distributes to the people under the form of bread alone, saying the words Corpus Christi ("the body of Christ") to each communicant, who answers "amen." Communion of the laity under either form alone has always been an occasional practice (consecrated bread was from the beginning reserved for the sick); but the difficulty of dealing with large quantities of wine led, in the east, to the practice of giving the laity a morsel of bread dipped in wine (intinction) and, in the west, to their being communicated under the form of bread only.

When all who wish have received, the priest collects into the chalice any crumbs and rinses it, first with wine and then with wine and water, letting the water flow over his thumbs and forefingers to wash off any minute particles that may be clinging to them. He drinks these ablutions and wipes out the chalice with a special cloth. (Until about the 13th century, the ablutions were a special cloth. (Until about the 13th century, the ablutions were a special cloth.) Next not drunk but were poured away in some suitable place.) Next the priest recites the communion antiphon, which was once a psalm sung during the distribution of communion; and the post-communion prayer of thanksgiving, variable according to the day. The dismissal *Ite, missa est* follows, but Mass no longer ends at this point; a last blessing and a recital of the prologue of St. John's Gospel were added in medieval times to close the rite.

Solemnizing of Masses.—There are four distinct types of Mass. (1) The most solemn form, which is also the most ancient, is High Mass (*Missa solemnis*). This is now usually celebrated with three priests, a number of servers or acolytes, and a choir. The actual requirements are for a priest, a deacon and a subdeacon, but in modern times—since the orders of deacon and subdeacon are merely the last steps to the priesthood and therefore filled only for a short time by students—it is normal for priests to take their parts. (2) A bishop's High Mass is called pontifical because he is the chief priest or *pontifex* (the papal Mass is a special form of this). Nonsolemn Mass, with one priest and one or more servers, can be either (3) low (*Missa privata* or *plana*; recited) or (4) sung.

The Ordinary and the Proper of the Mass.—Parts of the Mass are unvarying (*Ordinarium Missae*), and into them the variable parts (*Proprium Missae*), which change according to the day or feast, are fitted. The Ordinary of the Mass includes the *Kyrie*, *Gloria*, Creed, offertory prayers, preface (though there are 15 proper prefaces), *Sanctus*, canon, Lord's Prayer, fraction,

Agnus Dei, communion prayers, conclusion and last Gospel. The Proper of the Mass comprises the introit, collects, Epistle, gradual, alleluia (or their substitutes), sequence, Gospel, offertory verse, secret, communion verse and postcommunion prayers.

There are Masses with characteristic variations in the ordinary and with special propers for funerals and commemorations of the dead (requiem Masses); for weddings (nuptial Masses); for ordinations; and for other special occasions.

Action of Second Vatican Council.—By mid-20th century it was felt by many that the Latin Mass rite, almost static for 400 years and performed largely by clergy, acolytes and choir, afforded too little participation to the people and was too remote from the mentality of modern man for maximum profit to be drawn from Sunday worship. Pope Paul VI, on Dec. 4, 1963, formally promulgated a constitution on sacred liturgy of the second session of the second Vatican council, laying down that the intelligent participation of the laity in the Mass, characteristic of the earliest centuries, was to be restored. Comprehension was to be aided by simplification of the rite through the removal of duplications and confusing accretions and by bringing into prominence necessary elements that had become obscured. The selection of Scripture readings was also to be widened.

For these readings, as well as for those parts of the Mass intended to be said or sung by the congregation and possibly almost all of the Foremass, vernacular languages might be introduced at the discretion of regional bishops' conferences to be held during 1964, subject to the direction of the holy see.

Non-Latin Forms of Celebration.—Various small groups of Roman Catholics celebrate the Eucharist with almost the same rites as the autocephalous Eastern churches. This is because these usages originated before the breakup of Eastern Christendom; hence those autocephalous Christians who return to the Roman Catholic Church preserve in general eucharistic ritual, language and customs of the body from which they came. See ROMAN CATHOLIC CHURCH: *The Catholic Eastern Rites*. (F. Ds.)

THE MUSIC OF THE MASS

The Ordinary of the Mass.—Settings of the *Kyrie*, *Gloria*, *Credo*, *Sanctus* and *Benedictus*, and *Agnus Dei* have been created in the forms of chant, polyphony and concerted music over a period of nearly 1,400 years. The *Ordinarium Missae* contains not only those items mentioned above, which make up the standard polyphonic or concerted Mass familiar to musicians, but also a final section, either *Ite, missa est* or *Benedicamus Domino*, not always included in the usual musical settings. In the middle ages the texts of the Ordinary were not as standardized as they have been since the 16th century, and the texts sometimes varied from day to day: the tropes (or additions of music and text) to the *Kyrie*, *Gloria*, *Sanctus* and *Agnus* changed according to the feast or season. Although the trope texts are no longer in use, the numerous settings of the *Kyrie* in plainchant are still distinguished by their old titles.

The modern Roman *Kyriale* is a collection of chants for the Ordinary, the main part being a group of 18 composite Masses. The various chants are in different styles and modes, and they stem from different epochs in the development of Gregorian chant. Tradition and usage account for their manner or grouping, though no hard-and-fast rule need be observed. Chants from one Mass may be interchanged with chants from another, and to give added variety there follow a number of plainsong settings of every section of the Ordinary, including the *Credo*.

Florid settings for one, two or three voices of tropes to the *Kyrie*, *Gloria*, *Sanctus*, *Agnus* and *Benedicamus* were written down as early as the 13th century and formed part of the repertory of the Notre Dame school of Paris which spread rapidly throughout the Christian world. There is even a troped *Sursum corda*, which belongs neither to the sung Ordinary nor Proper but to the preface spoken by the celebrant. At first these different settings were combined with considerable freedom so as to constitute Mass cycles for daily use, and this custom persisted into the 14th and 15th centuries, when manuscript choirbooks often contained hundreds of individual settings grouped together under *Kyrie*, *Gloria* and so

on. The 14th century saw the beginnings of a tendency to paired movements, usually *Gloria-Credo* or *Sanctus-Agnus*, and about this same time the Masses of Toulouse, Tournai and Besançon give evidence of further progress in the combination of four or more items to make a unified Ordinary. In some cases these experiments were not entirely successful, but when Guillaume de Machaut wrote his Mass it became clear that homogeneous style and liturgical fitness were not incompatible.

Parts of Machaut's Mass were built on a plainsong *cantus firmus*, and this method of construction was followed by J. Dunstable, G. Dufay, J. d'Okeghem, J. Obrecht, Josquin Després, R. Fayrfax and many Renaissance composers up to the time of Palestrina and Victoria. There was, however, a gradual change from Masses containing at least one clearly instrumental part to those whose polyphonic texture was entirely vocal, even though instruments may have been used to double the voices. Early in the 17th century concerted music greatly influenced ecclesiastical music, and many of the Masses by T. Merula, M. A. Grancino, O. Tarditi and Francesco Cavalli prepared the way for the baroque extravagances of the Masses of Orazio Benevoli. In Germany the chief composers of Masses were H. I. F. von Biber, J. H. Schmelzer and J. C. Kerll, while in France the outstanding composer was M. A. Charpentier.

Operatic music inevitably made a profound impression on concerted Masses, with the result that elaborate solos began to be incorporated into the choral and orchestral background. Bach's B minor Mass was probably never used liturgically, although the Masses of J. A. Hasse, F. Durante, J. J. Fux, Haydn and Mozart successfully adorned the services of their time and place. Beethoven's C major Mass was conceived as a liturgical work, but his *Missa Solemnis* is basically a work for concert performance. Large-scale Masses continued to be written in the 19th century by Cherubini, Schubert, Weber, Liszt, Franck, Gounod and Bruckner, and in the 20th century some of them were occasionally heard in the concert hall if not in church. Toward the middle of the 20th century a sharp distinction arose between Masses written in imitation of the Renaissance style, such as those by L. Perosi, and the more original and forward-looking examples by G. F. Ghedini, F. Poulenc, Vaughan Williams, Benjamin Britten, Edmund Rubbra and Stravinsky.

The Ordinary of the Mass was not always assigned to voices, or voices and instruments. Sometimes the organist was allowed to alternate with the plainsong of choir or congregation, and composed settings for organ are generally termed organ Masses. Early 15th-century Italian and German organ Masses set the pattern for most subsequent developments, which gave rise to complete settings of the Ordinary by J. Buchner, P. Attaignant, Philip ap Rhys, G. Cavazzoni, C. Merulo, N. de Grigny, N. A. Le Bègue and F. Couperin, to name only the most important.

The Proper of the Mass.—As the items comprising the *Proprium Missae* vary according to the feast and season they are clearly more bound to the liturgy and its immediate needs than the Ordinary is. A Mass Proper has not made its presence felt in the concert hall, though it is of prime importance in the service of the church. Its principal sections are: introit, gradual, alleluia (or on certain occasions tract), sequence, offertory and communion. Once again the earliest noteworthy polyphonic settings are those of the Notre Dame school of Paris, beginning in the last decade of the 12th century. Leonin, and after him Perotin, set most of the great responsorial chants for two, three or four voices, and their lead was followed by English and Spanish composers. Isolated compositions are found in the 14th century, but no large-scale settings of the Proper preceded those of Dufay, presumably written from 1430 onward.

The seven choirbooks at Trent preserve many settings of the Proper, though these are not invariably grouped as a cycle; it was customary to keep texts of one kind together, as in collections of the *Ordinarium Missae*. Choirbooks similar in type to those of Trent, and again containing a large selection of items from the Proper, are to be found in Jena and Weimar, but the earliest and most ambitious venture of the 16th century was H. Isaac's *Choralis Constantinus*, printed at Nürnberg after the

composer's death. Isaac's polyphonic monument provided music for all the principal feasts of the church year as well as for the Common of Saints and Martyrs, and although there were other printed collections of the time (the Lyon *Contrapunctus* of 1528 and G. Rhau's editions of 1539 and 1545) the *Choralis Constantinus* is unrivaled in its scope and excellence.

Both Orlando di Lasso and Palestrina wrote complete cycles of the offertory, and many of their unclassified motets could be assigned to the Proper. But it was not until William Byrd's two books of *Gradualia* appeared in 1605 and 1607 that a truly great scheme made itself felt in the world of church music. Even then Byrd's work did not receive the recognition it deserved since England was no longer a Catholic country and the number of copies exported must have been small. The baroque era saw only isolated settings of texts for the Proper. The earliest made considerable use of divided choirs (*cori spezzati*) and reached a minor peak of excellence in the work of M. Zielenksi, S. Bernardi, G. F. Sances and F. Foggia.

The concertante style was exploited by J. Hofer, S. Mayr, V. Rathgeber, V. Ruffo, N. Jomelli, G. B. Martini and Michael Haydn, to mention only a few of a vast and active group of church composers. Subsequent contributions to the Mass Proper were, on the whole, desultory rather than broadly conceived, though contributions were made by a few composers of good standing. Settings of the Proper for organ, alternating with plainchant, are comparatively rare, but there is one notable and reasonably complete setting of the Proper for Easter day by the Tudor composer Thomas Preston.

The Requiem Mass.—The plainchant of the *Missa pro defunctis* combines parts of the Ordinary and the Proper: introit, Kyrie, gradual, tract, sequence, offertory, *Sanctus*, *Agnus* and communion. Not all of these are set in polyphonic and concerted requiem Masses; on the other hand, additions are sometimes made, as in Verdi's *Requiem* which ends with the responsory *Libera me*, taken from the burial service which follows the Mass. One of the earliest polyphonic settings is that of Okeghem; others followed in the 16th century, by Pierre de la Rue, Johannes Prioris, A. de Fevin, C. de Morales, F. Guerrero, Lasso, Palestrina and Victoria. Later settings by J. C. Kerll and H. I. F. Biber emphasized the dramatic element, especially in the *Dies Irae*, and this is largely true of the requiems by N. Jomelli and Mozart. Outstanding among 19th-century settings are those of Berlioz, Cherubini, Dvorak, Verdi, Bruckner and Fauré. Benjamin Britten's *War Requiem* (1962), based on a text consisting of both the Latin prayers and the war poems of Wilfrid Owen, was the outstanding work of this kind of the mid-20th century. See also CHURCH MUSIC; PLAINSONG; and references under "Mass" in the Index.

MASSA-CARRARA, a province in northwestern Tuscany, Italy, largely mountainous, lies between the Tuscan Apennines and the Tyrrhenian sea. Area 446 sq.mi., pop. (1961) 201,245. In the centre are the Apuan Alps, a small massif, world-famous for their marble quarries. The northwestern corner, the valley of the Magra river, is known as the Lunigiana district. The province was originally created in 1938 and was known as the province of Apuania until 1945 when it received its present name. The Cybo Malaspina family, long the feudal rulers of the area, built the splendid 16th-century fortress of Massa and a handsome palace in the city itself. Massa is now the capital (pop. [1961] 57,308 [comm.]). Carrara (pop. [1961] 63,741 [comm.]) has a sides being synonymous with the best marble of the world has a fine Romanesque-Gothic cathedral (12th-14th century), built in the Pisan style. The Rome-Genoa railway passes through the short

coastal section of the province; there are also rail and road connections with Parma and Lucca. (G. KH.)

MASSACHUSET, an Algonkian-speaking tribe that may once have numbered 3,000 and in the early 17th century were said to live in more than 20 villages distributed along the Massachusetts coast (see **ALGONKIAN TRIBES**). Before colonial settlement began, however, they were greatly reduced in number by intertribal warfare and by a pestilence in 1617, followed in 1633 by a smallpox epidemic which wiped out most of the few remaining members of the tribe, including its chief. Toward the end of the first half of the 17th century they became Christians and lost their tribal identity.

See F. W. Hodge (ed.), *Handbook of American Indians North of Mexico* (1959).

MASSACHUSETTS, popularly known as the Bay state or Old Bay state, was the sixth of the 13 original colonies that formed the United States. Its name, meaning "large hill place" or "at or about the Great Hill," came from the Massachusetts Indian tribe. The official motto of the state is *Ense petit placidam sub libertate quietem* ("By the sword we seek peace, but peace only under liberty"). The state flower is the trailing arbutus, commonly called the Mayflower. The state tree is the American elm and the bird is the chickadee.

The state of Maine—larger than the other five New England states combined—was part of Massachusetts until 1819. Vermont and New Hampshire now form the northern boundary of Massachusetts. To the east is the Atlantic ocean. On the south is the ocean, Rhode Island and Connecticut. New York forms the western boundary. Because of its peculiar form, these boundaries are only approximate in the east. Its main portion forms a parallelogram about 130 mi. from east to west and 46 mi. from north to south, its straight southern boundary being almost coincident with the parallel of 42° N. In the east, the state spreads out, extending considerably south and somewhat north of the lines of the parallelogram, the counties of Plymouth and Barnstable forming the peculiar southeast "pothook" of Cape Cod. The state extends approximately between the extremes of 41° 14' and 42° 53' N. Boston, the capital and principal city, is in about the same latitude as Rome. The total area is 8,257 sq.mi., of which 390 sq.mi. are water. Massachusetts ranks 45th in size among the states.

PHYSICAL GEOGRAPHY

Physical Features.—These can be understood in their full significance only by reference to those of New England as a whole. The Appalachian mountain barrier, which extends from southwest to northeast parallel to most of the eastern coast line of the United States, continues through western New England in the Berkshire hills and the Green and White mountains. From the base of these ranges a gently sloping upland descends south and eastward to Long Island sound and the Atlantic ocean. The only large river navigable for any considerable portion is the Connecticut, which flows southward from the Green mountains of Vermont to the sound. As Massachusetts in form is a long narrow strip extending westward from the ocean, it runs at right angles, so to speak, to these principal New England features of mountains and river. Its eastern two-thirds is mostly made up of the sloping upland. West of that the state is divided by the Connecticut valley. West of that again lie the mountainous western counties.

There are several small ranges, each with local names, in the Berkshires. The more eastern is that known as the Hoosac hills, which have an elevation of only 2,100 to 3,041 ft. and divide the valley of the Connecticut river from that of the smaller but more picturesque Housatonic. Bordering the lowlands of the Connecticut a few well-known hills rise to a marked height above the general level, such as Mt. Tom (1,202 ft.), Mt. Holyoke (935 ft.) and Mt. Toby (1,269 ft.). West of this, in what is known locally as more particularly the Berkshire region, are found such peaks as Mt. Williams (2,951 ft.) and Greylock (3,491 ft.), the highest point in the state. From the Connecticut valley eastward the elevations steadily decrease to the coast, and the extreme southeastern portion is low lying and sandy. There are a few exceptions, such

as Mt. Lincoln (1,238 ft.), Mt. Wachusett (2,006 ft.) and the Blue hills. These, like those mentioned in the western section, appear to be residual peaks of an original mountain range that covered the entire state in the geological era before the whole had been leveled to the plain which was then carved into its present features. The existence of this original mountain range is also indicated by the structure and extremely complicated disorder of the gneiss and crystalline schist of the uplands. On the other hand, the valley of the now much shrunken Connecticut river is composed mainly of shale and soft sandstone. The evidences of the glacial period occur everywhere, the entire state having been covered by the ice sheet, with resultant glaciation of the rocks, as far as the Cape Cod peninsula, where are found traces of the terminal moraine.

The eastern part of the state can be described almost wholly in terms of the junction of sea and land, though there is one small river, the Merrimack, important not because of its very short navigable portion but for the water power it provides by its fall. The coast line extends for about 250 mi., with a number of good harbours. The enormous water area included between the two points of Cape Ann and Cape Cod is known as Massachusetts bay, with the designation Cape Cod bay for its southern portion. Among the harbours, all of which are excellent, and popular yachting resorts, may be mentioned those of Salem, Gloucester, Marblehead, Boston and Provincetown on the east, and Buzzards bay on the south. The northern part of the eastern shore is somewhat rocky and picturesque, whereas the long pothook or encircling arm of Cape Cod peninsula (Barnstable county) is low and sandy. Almost the entire coast is lined with summer resorts. Those within a 30-mi. radius of Boston, however, were rapidly becoming year-round towns in the second half of the 20th century. Modern highways coupled with population growth are the main reasons.

At Woods Hole on Buzzards bay is the U.S. fish and wildlife service station with a marine biological laboratory. Leaving the mainland, there are several islands to the south, two of them, Martha's Vineyard and Nantucket, being of considerable size and importance. Martha's Vineyard, a little larger (about 9 by 20 mi.), has a good harbour which, aside from summer yachting, is resorted to by stormbound vessels avoiding the dangerous shoals that lie to the southeast of the state.

The physical features thus briefly described have had a marked effect upon the history of Massachusetts at every period. In the colonial days, when waterways provided the only means of travel, the absence of any large river leading to the interior retarded development of the sections lying back of the coast, prevented the development of the fur trade and led the people to look to fisheries and commerce for their livelihood, an influence that was strengthened by the rather poor soil of most of the state. The climate (see below) was another factor that prevented the growth of large estates and a slave economy as in the south. The broken character of the eastern upland has had a marked effect also, the richer valleys having afforded moderate ease and comfort, which resulted in conservative politics, whereas the "hill towns" were poorer, radical in politics and largely abandoned when a changed economic situation and western expansion opened new opportunities for their dwellers. The fact that the Connecticut river merely ran through the state, flowing thence into another, led the inhabitants of this richest of all sections to ally themselves rather with their neighbours to the south in Connecticut than with their own fellow citizens to the east. To the west of this, the mountainous and somewhat rugged land gave special character to its inhabitants, who have always shown themselves more democratic and radical than those in the mercantile towns of the seaboard. As a whole, the mountain barrier to the west long tended to isolate New England from the rest of the country, to preserve certain New England characteristics, which included a certain provinciality of outlook in which Massachusetts shared. Although railways overcame this isolation to some extent, the great traffic from the west goes to New York city rather than to Boston, and both commerce and manufactures declined relative to those in competing states. Massachusetts lost much of its textile industry in the 20th century, but it rapidly diversified and attracted new firms in

the electronic and chemical industries. The beautiful scenery and changing seasons attracted more and more people, and the automobile brought unexpected prosperity to villages that shortly after 1900 seemed doomed.

Climate.—Massachusetts has four distinctive seasons. It is a rare winter that does not have at least one severe snowstorm throughout the state. It is not uncommon, however, for the western part of the state to have severe storms while the southern section—Cape Cod and the islands—enjoy moderate weather with little or no snow. Spring often brings the extremes of winter and summer with generous amounts of rain. July and August are the hottest months, with September offering relief with dry, crisp air. Mean averages in the middle of the 20th century at Boston were 30.4° F. (−0.9° C.) in the winter and 70.3° F. (21.1° C.) in the summer. Extremes recorded were 106° F. on July 4, 1911, in Lawrence, and −34° F. on Jan. 18, 1957, at Burch Hill dam. The average annual precipitation for the state is 43.06 in. along the coastal area, 44.64 in. in the central area and 45.14 in. in the western area.

Vegetation and Animal Life.—There is little that is distinctive in either animal or plant life as differentiated from New England as a whole. The state is a meeting place, however, for many southern and northern species of which it forms, respectively, the northern and southern limits. It is, for example, the northern limit of such trees as the holly and tupelo, the latter occasionally found in southern New Hampshire also. There is a small colony of prickly-pear cactus in Nantucket. It is also the northern limit of many insects, notably the 17-year locust. Among the birds likewise limited are the seaside sparrow, blue-winged warbler, prairie warbler and quail. On Martha's Vineyard there was a colony of the heath hen, until 1929 or 1930, but it is now extinct.

Most remarkable from the standpoint of its fauna and flora is the influence of Cape Cod, which stretches out to sea and deflects the current of the Gulf stream. To the south of the cape are found many southern fishes and other marine creatures, including the Portuguese man-of-war. On the north side of the cape the fish and invertebrates are entirely different; it is said that no other barrier makes so sharp a dividing line in ocean animal life.

Parks.—There are more than 100 state parks, forests and other state reservations. October Mountain state forest, with 13,723 ac. in western Massachusetts south of Pittsfield, is the largest in the state. Savoy state forest (10,956 ac.), farther north on the Hoosac range, offers scenic attractions and various camping and recreational facilities; Myles Standish state forest covers about the same area in the eastern part of the state south of Plymouth. State parks include Clarksburg (near Mt. Greylock), Cochituate (includes the lake of the same name west of Boston) and Pilgrim Springs park.

The Cape Cod National Seashore recreational area, comprising 50 mi. of coastal dunes and beaches, was authorized in 1961.

HISTORY

Exploration and Early Colonization.—It is uncertain when Massachusetts was first visited by Europeans. In spite of conjecture of visiting Norsemen around A.D. 1000, there is no proof of anyone's having been there before 1602, when the English navigator Bartholomew Gosnold visited Massachusetts bay and named it Cape Cod. Two years later Samuel de Champlain explored the coast and in 1614 John Smith also did so, naming many of the points along it. After that, visits became more frequent, but it was not until many years after other settlements had been made in America that a permanent colony was planted there at Plymouth, in 1620. Certain separatists from the Church of England had fled from England to the Netherlands several years before and from there decided to migrate to the new world. After considering Guiana and other places, they determined to try the territory owned by the Virginia Company of London, and financial assistance was received from colonizing speculators in London. When the "Mayflower" sailed, of its 102 passengers only 35 came from the Leiden religious group and 67 from London. Before landing, the leaders of the Pilgrims drew up the famous Mayflower Compact to serve as the basis of government. There was no intention

of making a new departure in the direction of a democratic constitution, and the short document was merely a modification of the customary form of church covenant to meet the temporary crisis in an unfamiliar situation. (See "MAYFLOWER.") Because of stress of weather or some other, unknown cause, the colonists landed in Massachusetts instead of in the Hudson river area, then included in the domain of Virginia. They had no other government than this formed by themselves, and the pure democracy thus inaugurated and later modified was accidental. It became, however, the precursor of innumerable other written covenants in New England, forming the basis of town and church government there. (See also NEW ENGLAND.)

The troubles of the first winter were severe, and half the colony died, including Gov. John Carver, whose place was taken by William Bradford. Indian tribes in the Plymouth area had been decimated by illness a few years earlier and the settlement had little trouble on that score. Fields earlier cultivated by the Indians were of considerable help to the colonists, who were ill fitted to carve farm land from the forests. The contract with the London promoters had called for ownership of property in common, but this was soon modified in favour of individual property. Although the colony managed to survive its initial difficulties and become modestly comfortable, it was never financially successful and eventually all connection with the English company was terminated. After the adjustment of accounts with its financial sponsors, the colony succeeded in getting grants defining its territorial boundaries, and gradually the village of Plymouth threw off other little settlements, such as Scituate (incorporated 1636) and Duxbury (incorporated 1637), but was finally absorbed into the larger and more powerful Colony of Massachusetts Bay in 1691.

Soon after the Plymouth settlement was made others were established along the coast, mostly by individuals, a number of whom from 1625 onward settled around Boston harbour. A small fishing company tried to establish a foothold and business on Cape Ann, which was, the forerunner of a much more important colonizing movement than any yet made in North America. In England it was a time of much change and unrest, quite as much political and economic as religious. The Puritans were drawn to a great extent from country gentlemen and middle-class businessmen, all of whom were feeling the stress of the times severely (see PURITANISM). There was a great migration of the discontented to the new world, a migration by no means confined to New England. Between 1620 and 1642, for example, 18,600 persons went to Barbados as compared with only 14,000 to Massachusetts, and 18,000 went to other West Indies islands as compared with fewer than 4,000 to the rest of New England. The Massachusetts settlement was thus merely an episode in a much broader movement.

The Massachusetts Bay Colony.—Certain Puritans in England became interested in an attempt to revive the defunct fishing company at Cape Ann, and in 1628 a patent was received from the Council for New England and a number of settlers were sent out under John Endecott as governor. Meanwhile the number in England interested in a Massachusetts venture had increased, and in 1629 a rather strong group, including John Winthrop, obtained a charter as "The Governor and Company of the Massachusetts Bay in New England." The grant was similar to that of the Virginia company in 1609, the patentees being joint proprietors, with rights of ownership and government. The intention of the crown was evidently to create merely a commercial company with what, in modern parlance, would be called stockholders, officers and directors, but by a shrewd and legally questionable move the patentees decided to transfer the entire management and the charter itself to Massachusetts, thus paying the way not only for making the management local but also for the unwarranted assumption, pregnant with most important consequences, that the charter for a commercial company was in reality a political constitution for a new government with only indefinite dependence upon the imperial one at home.

The religious motive was but one among others inducing even the leaders to emigrate to America. It was undoubtedly important, but even it looked merely to the establishment of a community in which the emigrants would be free to worship as they

themselves wished, not to establish in any way a refuge for those who might wish to worship differently. Indeed, throughout the whole colonial period, the leaders of the colony fought religious liberty with every weapon in their power. The economic motives were also strong (as Winthrop clearly indicated in writing in his own case), the sudden increase in the cost of living in England, with consequent unsettlement of established habits and social position, being a leading factor.

In the summer of 1630 a fleet of ships transported nearly 1,000 emigrants, including Winthrop as governor and Thomas Dudley as deputy governor, to Massachusetts bay, where they settled the towns of Boston, Charlestown, Dorchester, Medford, Watertown, Roxbury and Lynn. Such leaders as Winthrop, Dudley, Endecott and the Rev. John Cotton were strongly opposed to democracy, were zealous to prevent any independence in religious views and had no trust in the people at large. Opposition showed itself now and then in the case of individuals, the general court or even a town (as Watertown, which protested a tax levy).

Religious Disputes.—The first of the more noted cases was that of Roger Williams, who was banished from the colony and settled in Rhode Island (1636). Almost simultaneously occurred the so-called Antinomian controversy in which Anne Hutchinson (q.v.) and Henry Vane the younger were the protagonists and which ended in the banishment of Mrs. Hutchinson and the return of Vane to England. There was much criticism in England, even among the friends of the colony, of the policy of repression adopted by the leaders, lay and clerical, but they pursued their course until halted by royal authority a generation later.

The harshness of rule, narrow-mindedness and self-satisfaction, which became characteristic of the Massachusetts colony, cannot be ascribed wholly to Puritanism. Much of it was motivated by a desire for profit. As has been said, it was a period of great Puritan emigration and all the colonies both on the American mainland and in the West Indies were strongly Puritan in tone at first. In the south and on the islands, differing climatic and other conditions induced modifications in cultural life and thought, but even in New England both Rhode Island and Connecticut were far more liberal than Massachusetts.

Extension of settlements brought on troubles with the Indians and in 1637 there occurred the war with the Pequots in which that people was practically annihilated. In the same year a synod of the clergy, held at Boston, listed 82 blasphemous, erroneous or unsafe opinions held in the colony. In 1643 a loose confederation of the four colonies of Massachusetts, Connecticut, Plymouth and New Haven was effected under the title of the United Colonies of New England. It performed some useful work but its policies were largely dominated by Massachusetts and it lost influence.

In 1644 laws were passed against the Baptists and several of them were cruelly dealt with. The Quakers also were persecuted, more particularly from 1656 to 1662, four being put to death and many others whipped, imprisoned, branded or banished. Finally, owing partly to a revulsion of public feeling and largely to action by the English crown, a stop was put to the worst forms of persecution. During the English Civil War and the Cromwellian period, the colonies had for the most part been left to go their own way, and Massachusetts had arrogated to itself an almost complete independence of the home government. It was obvious according to the ideas of the time that if the colony were to remain part of the empire a closer dependence would be essential, and after the Restoration it was decided to send out a royal commission to investigate conditions. In 1665 the commission visited New England, and the following year the king sent a circular letter to all the colonies, expressing dissatisfaction with Massachusetts in only. There was, indeed, a considerable and respectable party in the colony itself that was opposed to the extreme pretensions of the local government. That government, however, trusting to distance and the preoccupation of England with the European war, pursued its course.

In 1675 there occurred a second and much more serious Indian war, known as King Philip's War, caused by the grasping land policy of the colonies and the desperation of the Indians at seeing themselves more and more hemmed in by the whites. It was an

inevitable conflict, and although the whites were victorious they suffered severely. It was said that 1 man in every 16 of military age was killed and it was long before the frontier recovered. Meanwhile the case of Massachusetts was again taken up by the English government. The colony adopted the method of evasion and delay in meeting charges and complying with orders. This policy resulted in the annulment of the charter in 1684, in leaving the colony defenseless against the king and with few or no friends in England to defend the course it had taken. In some respects, such as the end of the exclusion of nonchurch members from the franchise, the cause of liberty gained by the change.

Royal Government.—In 1686 a royal government was inaugurated by the arrival of Joseph Dudley, a native of Massachusetts, as president of a provisional government until a new one could be devised. He was soon supplanted by Sir Edmund Andros, whose government extended over all New England and New York. Although he was by no means the "tyrant" whom the earlier patriotic historians painted, he was lacking in tact and in the qualities of wise statesmanship, and his situation was an extremely difficult one. When word came that the Stuart dynasty had been overthrown in England in favour of William of Orange, a mild revolution occurred in Boston, and Andros and most of his government were imprisoned. Finally, in 1691 a new charter was procured for Massachusetts, to whose territory it added the province of Maine and the former colony of Plymouth.

Although the new charter provided for a royal governor and in other ways greatly diminished the power of the old theocratic party, it was a more reasonable governmental instrument than the anomalous commercial charter which the colony had for so long tried to twist into a political constitution. The first royal governor was a New England man, Sir William Phips, who had led an unsuccessful attack on Quebec in 1690. Massachusetts had carried out an easy raid upon Acadia, which had inspired hopes of a larger conquest of French territory, with the sole result of almost bankrupting the colony by a debt of £200,000.

The last decade of the 17th century was also marked by the witchcraft delusion, mainly in Salem village, during 1691–92. In all about 32 persons were executed, one by the horrible medieval penalty of being pressed to death under heavy weights. After the end of that delusion, the life of Massachusetts took on a more modern tinge. Not until 1957, however, was a resolve passed by the state legislature declaring that the proceedings convicting one Ann Pudeator and certain other persons in 1692 of witchcraft had been shocking and the result of a wave of hysterical fear of the devil, even if lawful under the province charter. Connecticut had shown the way to civil, and Rhode Island to religious, liberty. If the far more powerful colony of Massachusetts cannot lay claim to having been a leader in either of these directions, its founders had established the strongest colony in North America in their search for profits, had made creditable beginnings in public education, had developed the system of town government and had laid the foundation for the Congregational Church. Although the results of the intellectual repression of its first century were long to be felt, with the opening of the new century the colony swung more and more into the growing liberalism of thought of the 18th century.

18th Century.—The colony also shared more in the larger life of the empire. Several times, notably in the unfortunate expeditions against Jamaica (1702), against Canada (1709–11) and Cartagena (1740), Massachusetts troops played an honourable part, and to that colony must be given the main credit for the capture of Louisburg from the French in 1745. In the French and Indian War its soldiers also took part in the expedition against Oswego, took the chief part in the capture of Acadia and also shared in the Crown Point and second Louisburg attacks. Meanwhile, the colony had been making rapid strides in wealth and was becoming markedly self-conscious politically. There had been serious trouble with the currency earlier in the century, due to the colonists' insistence, perhaps necessary, upon the use of large amounts of paper money, in which it was opposed by the English government. This trouble culminated in a crisis, including rioting, under Gov. Jonathan Belcher in 1740, but the repayment to the colony by

England of about £183,000 in sterling to cover its expenses in the capture of Louisburg enabled it to retire about £2,000,000 of its depreciated bills and establish itself on a firm money basis, a fact of great importance in its subsequent commercial development. Fortunes were accumulating, business operations were growing much larger in scale, Harvard had become liberal in thought and Connecticut, not Massachusetts, had become the last stand of the old religious ideas.

During the war there had been much smuggling and trading with the enemy, and the British government became more stringent in trying to enforce trade regulations. In 1756 it introduced a system of general search warrants, such as Massachusetts itself had had in force for eight years. Merchants who saw their profits endangered protested, and in 1761 James Otis made his famous and impassioned attack in court upon these writs of assistance, the strict legality of which was hardly open to question. Following the peace of 1763 and the need for readjusting the cost of maintaining and defending the empire, came the attempts to solve the problem.

Pre-Revolutionary War.—In 1765 Massachusetts was prominent among the colonies which resisted the Stamp act. Samuel Adams of Boston, one of the ablest agitators and propagandists any country has produced, set himself to keep alive the flames of discontent, having made up his mind that the colonies should be wholly independent of England. In his skilful manipulation of public opinion and emotion, and in his organization of the committees of correspondence, he probably did more than any other man to arouse the opposition of certain elements against England and to prevent the possibility of any reconciliation.

In 1768 royal troops were stationed in Boston and on March 5, 1770, a clash occurred between them and some citizens, of whom five were killed. The soldiers had been constantly subjected to taunts and abuse and on the whole had behaved well. In this incident a small mob had been the aggressors. Officers and men at once surrendered to the civil authorities and upon trial by the local court were acquitted, except two who received slight penalties for technical homicide. Samuel Adams and his party made the most possible of the "atrocious" and dubbed it the "Boston massacre."

In 1773 occurred the Boston Tea Party, in which a band of citizens disguised as Indians boarded ships carrying tea and threw it overboard. In retaliation for this wanton destruction of private property parliament passed the Boston Port bill, closing the port to commerce. (See also BOSTON.) The increasing agitation and violence of the mobs during this decade presaged more serious armed conflict.

Revolutionary War and After.—Gen. Thomas Gage was made governor and in April 1775 sent an armed force to Lexington and Concord to destroy military stores gathered at those places. The force was attacked and completely routed by the country people, and Gage was practically besieged in Boston. In an effort to release himself the battle of Bunker Hill was fought—actually on Breed's hill—June 17, resulting in a military defeat but a psychologically victory for the Americans. The British loss was exceedingly heavy. In July Washington arrived at Cambridge to take command of all the troops, and soon after the scene of war shifted from Massachusetts and no important military action occurred within it for the rest of the struggle. During the whole of it Massachusetts contributed more liberally than any other colony in men and money, though military leadership, except for Gen. Henry Knox and Gen. Benjamin Lincoln, passed to other hands.

Two years of prosperity following the signing of peace in 1783 soon gave place to serious financial difficulty, particularly among the poor and heavily taxed farming class. Violence occurred in most counties and became especially serious in the western ones. Owing largely to the failure of the legislature either to suppress the insurrection or to redress grievances, the revolt gained headway. Many former Revolutionary soldiers and officers took part in it, among others Capt. Daniel Shays, and because of his leadership the movement became known as Shays's rebellion. It was finally put down by aid of heavy forces under General Lincoln.

The incident was important as frightening the moneyed classes into accepting more readily the new federal constitution. This

was ratified by only a very small majority. After its adoption the state became strongly Federalist in politics.

19th Century.—A group of leading politicians, known as the "Essex Junto" and including such men as Fisher Ames, George Cabot, Timothy Pickering, John Lowell and others (all opponents of democracy and strongly reactionary), long dominated the politics of the state. They were utterly out of sympathy with the principles of the party in national power after 1800 and with the policy of war against England in 1812. As a commercial community the state suffered heavily from the embargo measures preceding the war and it was characterized by extreme sectionalism and antinationalism during the war. Although New England held most of the specie of the country, it refused, in the main, to subscribe to the war loans and Boston took only \$75,000 of that of 1813 as compared with \$7,000,000 subscribed in Pennsylvania. Although great numbers of its citizens supported the government, the policy of the state as a whole was distinctly obstructionist. Rumours of secession, which had been heard at intervals from 1800, seemed to find confirmation with the convening in 1814 of the Hartford convention to consider grievances against the federal government; it was mainly dominated by Massachusetts. The convention adjourned, however, doing little harm except to the reputations of those who had attended. The state also opposed the Mexican War of 1846-48 as it had the policy leading to it.

The period 1830-40 witnessed great social changes, among others the rise of the factory system and the substitution to a great extent of imported foreign for native American labour. It was a period of intellectual ferment and of social experiment. Utopian communities, such as Brook farm, were undertaken, and although they all ended in failure they left their mark on the thought and idealism of the times.

Under the lead of William Lloyd Garrison and Wendell Phillips, Massachusetts was in the van of the abolitionist movement. Such citizens as C. F. Adams and Charles Sumner took leading parts in the formation of the Free-Soil party, and when at last the Civil War came the state rallied to the support of the federal government in a spirit utterly different from that which had marked the two preceding ones. It has been stated that of the 159,165 men whom the state sent to the war fewer than 7,000 were drafted.

Post-Civil War and Later History.—After the war the Republicans maintained a fairly continuous control until 1911. The industrialization of the state and the increasing domination of the cities by immigrant peoples strengthened the Democrats, and, except for the period 1916-28, they dominated the state in national elections. In 1928 Massachusetts was among the few supporters of Alfred E. Smith, and in all presidential elections from 1932 through 1948 continued to vote Democratic. Dwight D. Eisenhower won the state for the Republicans in the presidential elections of 1952 and 1956. As Republican governor in 1919, Calvin Coolidge (elected U.S. vice-president in the following year) came to national prominence when he put down with state troops a strike by the Boston police. Republican governor Christian A. Herter (1953-57) was named U.S. secretary of state by President Eisenhower in 1959. Herter was succeeded as governor by Democrat Foster Furcolo in 1957. In 1960 Sen. John F. Kennedy of Massachusetts, Democrat, carried the state and the country in the presidential elections. In 1964 his brother Edward M. Kennedy became a Massachusetts senator. In 1966 the state elected Edward W. Brooke, Republican, as the first Negro U.S. senator since Reconstruction.

Massachusetts Men and Women.—The influence of Massachusetts in life of the nation has been out of all proportion to its size and population. The roll of historians has been notable including John Winthrop, William Bradford, Thomas Hutchinson, Bancroft, Sparks, Prescott, Motley, Parkman, Thayer, Henry Adams (historian and philosopher) and Rhodes by adoption.

In poetry Massachusetts produced R. H. Dana, Bryant, Longfellow, Whittier, Lowell, Holmes and Amy Lowell; in philosophy and theology, Jonathan Edwards, Channing, Emerson, Theodore Parker, William James and Mary Baker Eddy; in fiction, Harriet Beecher Stowe and Hawthorne; in education, Horace Mann, Charles W. Eliot and James Conant; in oratory and states-

manship, James Otis, John Adams, John Quincy Adams, Webster, Rufus Choate, Everett, Sumner and Wendell Phillips; in social reform, S. G. Howe and B. F. Sanborn; and in law, Story, Parsons, Shaw, Holmes, Gray, Brandeis and Frankfurter.

GOVERNMENT

The first government, other than that of the Plymouth settlement, was based upon the charter of 1629, which was intended to be merely the charter for a commercial company but which was twisted by the colonists into a political constitution.

The system of "towns" created became the most characteristic feature of the New England system. The word meant a "township," an area of considerable extent that might include several settlements, villages, etc. Each township had the right of sending deputies to represent it in the general court, as the legislature was styled. The affairs of the towns, including election of officers and representatives, were conducted in town meetings at which all citizens had the right to speak although the franchise was for long limited by religious requirements. The town meeting was a political school of prime importance and although the system has less significance now it has been abandoned slowly and with reluctance even in the larger places; Boston, for example, refused incorporation as a city until 1822, when it had a population of 47,000. There still remained, however, over 300 towns compared with only 39 cities in 1960. Among the larger towns, based on 1960 population figures, were Brookline, Arlington, Weymouth, Watertown and Framingham.

Representative government dates from 1634 and the general court (the legislative body) was divided into two chambers in 1644. The old charter was annulled in 1684 and a royal one, with a governor appointed by the crown, substituted in 1691. The government functioned under this until the Revolutionary period when, first, committees and, next, a provincial congress took over the duties. The constitution, adopted in 1780 and which calls the state a commonwealth, is the oldest of all state constitutions still in force. It has been amended frequently. Townships ceased to be represented as such after 1856. The franchise is enjoyed by citizens over 21 years old.

The last religious test even for officeholders was abandoned in 1821 and the last remnant of a property qualification in 1891 and sex distinction in 1924. A slight educational test can still be enforced. Massachusetts was the first state to adopt the blanket ballot, in which the names of candidates are arranged alphabetically without party columns. A relic of colonial times is the council, a body elected to represent divisions of the state to assist the governor in executive functions. Its major power lies in its veto over gubernatorial appointments and pardons. In 1916 the jurisdiction of district or municipal courts was extended to run throughout the state.

Massachusetts has been a leader in the creation of boards and commissions whose functions extend to almost every department, such as the boards of education (1837), agriculture (1852), rail-road commissioners (1869), health (1869), statistics of labour, fisheries and game, charity (1879), insanity (1879) and the dairy bureau (1891). Others have to do with prisons, highways, insurance, banking, ballot laws, voting machines, gas and electric companies, conciliation and arbitration in labour disputes, registration in dentistry, medicine and pharmacy, inspection of food and drugs, etc.

Almost all state employees are under civil service regulations, even in the smaller political subdivisions. There are rigid laws to prevent stock watering in all corporations of a semipublic sort. The Torrens system of land registration was adopted in 1898 and a court created for its administration. Municipal ownership of public utilities, particularly gas and electric light works, is permitted. There were more than 40 publicly owned utilities after mid-20th century. The state did notable work for municipalities in such matters as roads, docks, parks and water supply.

Finance.—In addition to real and personal property taxes, major sources of revenue in the 1960s were the state income taxes, corporation taxes, and motor-vehicle and trailer excise taxes. In 1959 the state began a payroll withholding system for state in-

come taxes similar to that for federal income taxes.

POPULATION

In 1790 the population was 378,787. It grew to 994,514 by the census of 1850, and to 2,805,346 fifty years later. It was 4,316,721 in 1940, 4,690,514 in 1950 and 5,148,578 in 1960. The population in 1960 was nearly twice what it was in 1900.

In 1960 the state had 11 standard metropolitan statistical areas: Boston, Brockton, Fall River, Fitchburg-Leominster, Lawrence-Haverhill, Lowell, New Bedford, Pittsfield, Providence-Pawtucket, Springfield-Chicopee-Holyoke, and Worcester. These areas had a total population of 4,408,687 or 85.6% of the total population of the state. In October of 1963 these areas were redefined, bringing the total population to 4,467,964 or 86.8% of the state total.

The table gives comparative population figures for towns and cities over 5,000.

In 1960 the population per square mile was 623.5 compared with 568.1 in 1950; in 1950 it was 50.7 for the United States as a whole and in 1960 it was 49.6. In 1960 the population breakdown for Massachusetts was 4,302,530 urban, and 846,048 rural. There were 1,534,732 households in 1960. Ten years before there were 1,307,450 households with an average of 3.9 persons per household.

Of the total population there were 2.4% nonwhites in 1960. The six leading countries of origin of the 576,452 foreign born in 1960 were: Canada, Italy, Ireland, the United Kingdom, Poland, and the U.S.S.R. There were 2,662,343 females and 2,486,235 males in 1960. Of the total, 11.1% were over 65 years of age and 77.8% of those over 14 years of age were in the labour force.

EDUCATION

In the colonial period Massachusetts took the lead in popular education and was the first colony to found a college, but at no time in that period could Harvard compare with the new world universities at Mexico City or Lima, Peru. The quality of New England colonial education has been greatly overestimated.

The real beginning of the state's modern system dates from about 1840, when the extremely bad situation everywhere in the schools of the country had aroused great criticism. At that time 29 of the richest towns in the state maintained no schools at all as they should have in accordance with the law. The school board was organized in 1837, and under the leadership of Horace Mann conditions improved rapidly. The system was still conducted in the second half of the 20th century under the general laws relating to education passed in 1920, with amendments.

There is a department of education "under the supervision and control of a commissioner of education, and an advisory board of education of six members, of whom at least two shall be women and one shall be a school teacher." The commissioner and the board members are appointed by the governor and council. The system includes common, high and normal schools, and all have a high reputation. Manual training from 1894 was part of the curriculum in all municipalities of more than 20,000 population. The state agricultural college at Amherst (incorporated 1863) became the University of Massachusetts in 1947. The first normal school (teachers' college) in the country was that founded at Lexington in 1839; a number of others were established later.

There are many private secondary schools of high standing, such as Phillips academy in Andover, and schools in Groton and Mount Hermon. The Roxbury Latin school, founded in 1645, is one of the oldest in the United States. Of the higher institutions of learning, besides Harvard (1636), may be mentioned Williams college (1791) at Williamstown, Amherst (1825) near Northampton, Boston university (Methodist Episcopal) and Boston college (Roman Catholic) at Boston (1839 and 1863), Tufts university (1852) at Medford, Clark university (1887) at Worcester and Brandeis university (1947) at Waltham. For women there are Mount Holyoke (1837) at South Hadley, Smith college (1871) at Northampton, Wellesley college (1870) near Boston, Simmons college (1899) in Boston and Radcliffe college (1879) in connection with Harvard. Technical instruction is at Worcester Polytechnic institute (1865), Worcester; the Massachusetts Institute of Technology (1861), Cambridge; and other schools.

Massachusetts: Places of 5,000 or More Population (1960 census)*

Place	Population				
	1960	1950	1940	1920	1900

Note Dash indicates place did not exist during reported census, or data not available.

collections of the laws of foreign countries; the Boston Athenaeum, including Washington's library; the New England Historic Genealogical society library, mainly devoted to family history; various libraries connected with Harvard university; Essex institute library, Salem; and the American Antiquarian society library, Worcester, with the finest collection of bound newspapers in the United States. There are other important technical libraries and many general ones of 100,000 or more volumes scattered throughout the state.

Museums and Historic Places.—Massachusetts has a wealth of museums and historic houses and buildings. The Museum of Fine Arts in Boston (1870) has what many consider the most important collection of Asian art in the western world. The Boston Museum of Science (1949) is an outgrowth of the Museum of Natural History (1830). Other museums to be found in Boston include the Isabella Stewart Gardner museum, the Institute of Contemporary Art, the Children's museum and the Children's Art Centre, Inc.

More than 175 museums and houses in the state are of historic interest. They reflect not only early life in New England but the interest created in the rest of the world during the days of the clipper ships that carried Massachusetts commerce to all parts of the globe. At Plymouth is the Plimoth Plantation, which contains the "Mayflower II" and has early Pilgrim dwellings on exhibition. At Sturbridge village in the western part of the state is a reproduction of a New England village of 1790. It contains old homes, shops and mills. There are demonstrations of spinning, weaving, cabinetmaking, furniture finishing, pottery, metalwork, printing, gristmilling and blacksmithing. There also are exhibits of the period. At West Springfield in southwestern Massachusetts there is another New England colonial village.

Other historic sites and places of special interest are covered in articles on Cambridge, Concord (the home of Emerson, Thoreau and other literary figures), Deerfield, Gloucester, Lexington, Marblehead, Martha's Vineyard, Nantucket, North Adams (the site of Fort Massachusetts), Provincetown, Quincy, Salem and Stockbridge.

HEALTH, WELFARE AND CORRECTIONS

Many private charitable corporations report to the state department of public welfare, and a large number of private infirmaries are subject to visitation by an inspector from the department. The Perkins Institution for the Blind is particularly notable for its historical association with Samuel Gridley Howe. Under the department of public welfare is the state infirmary at Tewksbury (1866). Under the department of public health are four tuberculosis sanatoriums at Rutland, Westfield, North Reading and Lakeville. The Pondville hospital is for cancer patients. The Massachusetts Hospital school is for the care and education of crippled and deformed children. The Lemuel Shattuck hospital is a chronic disease institution. Under the department of mental health are state hospitals for the insane at Worcester, Taunton, Northampton, Danvers, Westborough, Boston, Grafton, Medfield, Waltham and Foxborough, and a colony at Gardner; Monson state hospital for epileptics at Palmer; schools for the feeble-minded at Waverly, Wrentham and Belchertown; the Walter E. Fernald State school at Waltham; and the Massachusetts Mental Health centre (Boston Psychopathic hospital).

The department of correction has a reformatory for women at Framingham, a state reformatory at Concord for men, a state prison at Walpole, prison camps at South Carver, Monroe and Warwick, a state farm at Bridgewater and a state prison colony at Norfolk. A modern state prison at Walpole replaced an ancient prison at Charlestown; many other penal plants, however, were in need of repair or replacement in the second half of the 20th century.

THE ECONOMY

Agriculture.—Conditions of soil and climate in Massachusetts are favourable for the raising of apples, small fruits, berries, potatoes, onions, market-garden vegetables and some kinds of tobacco. The average yield per acre for potatoes, oats and tobacco

Libraries.—The Boston Public library (first city public library to be entirely supported by taxation) is one of the great scholarly libraries of the country open to the public, specializing in Shakespeare, Americana and Spanish literature. Other notable libraries are the Massachusetts Historical society's library, rich in Americana manuscripts; the state library, with one of the finest existing

is higher than the national average. In the 1960s the 11,000 farms in the state were less than half the number at the end of World War II, and the total acreage decreased to about 1,100,000 as compared with 2,100,000 ac. in 1945. The average value per farm more than doubled in that period, however, increasing from about \$7,000 to more than \$16,000. Dairy products and eggs are the leading farm products in the state.

Industry.—There was little manufacturing in Massachusetts before the American Revolution. The state, however, quickly became the leader in the textile industry as well as other industries of importance. The first cotton mill was established at Beverly in 1788 and the first woolen mill at Byfield in 1794. The first power loom was set up in 1814 at Waltham. With the improvement in machinery and the development of water power, the great centres of Lowell, Lawrence and Fall River arose in the 1830s. In the 20th century vast changes occurred in the industry of the state as a result of the transfer of much of the textile business to the south.

The leading industries in the 1960s were machinery, including electrical machinery manufacture; textile mill products; food and kindred products; and leather and leather goods. The state is noted for its footwear industry. After mid-20th century over one-third of the persons employed worked in manufacturing industries; the next largest field of employment was wholesale and retail trade.

Minerals.—The chief products of quarries in the state are sand and gravel building stone, monumental stone, traprock and limestone. The principal granite quarries are in Quincy, Rockport, Westford and Milford, although granite is a common rock in Massachusetts and is found in every county except Barnstable, Dukes and Nantucket.

Commerce.—The cod fisheries have always been of prime importance in the economics of the state and formed one of the bases of the earliest commerce to Europe. Until 1785 when trade was opened with China and 1788 when trading began with the American northwest coast, trade was mainly with Europe, Africa, and the West Indies and American coast ports. Shipbuilding was always an important industry and with the rise of the clipper ships and the rich trade to the orient, merchants of Salem and Boston grew rapidly in wealth. Owing to great changes in the United States and in transportation facilities to the interior, Massachusetts fell behind many other states in foreign commerce.

Transportation and Communication.—In the 1960s the state was served by over 1,500 mi. of railroad track, 2,350 mi. of paved state highways and 25,000 mi. of all roads within the state. There were more than 100 municipal, commercial and private airports, of which Logan International airport in Boston was the most important.

In addition to separate articles on most places and persons of historical interest mentioned under *History*, see also references under "Massachusetts" in the Index.

BIBLIOGRAPHY.—Lengthy and important bibliographies are to be found in J. Winsor's *Memorial History of Boston* (1880–81) and in his *Narrative and Critical History of the United States* (1887–89). J. T. Adams, *History of New England*, 3 vol. (1927) (originally published separately with distinct titles), contains footnote references to several thousand works on New England, largely Massachusetts. Other works are: William Bradford, *History of Plymouth Plantation* (various editions; reprinted 1952); Cotton Mather, *Diary*, 2 vol. (1957); J. Winthrop, *History of New England, 1630–1649* (journal), 2 vol. (1908), and *Papers*, 3 vol. (1943–47); the publications of the Prince Society, notably the *Hutchinson Papers* (1865), the *Andros Tracts* (1868–74) and the *Randolph Papers* (1898–1909); Henry Adams, *Documents Relating to New England Federalism* (1877); W. Walker, *Creeds and Platforms of Congregationalism* (1893); L. K. Mathews, *Expansion of New England* (1909); A. E. Morse, *The Federalist Party in Massachusetts* (1909); W. A. Robinson, *Jeffersonian Democracy in New England* (1916); A. M. Schlesinger, *The Colonial Merchants and the American Revolution* (1918); R. G. Usher, *The Pilgrims and Their History* (1918); S. E. Morison, *The Maritime History of Massachusetts* (1921); R. J. Taylor, *Western Massachusetts in the Revolution* (1954); R. E. Brown, *Middle-Class Democracy and the Revolution in Massachusetts, 1691–1780* (1955); P. G. E. Miller, *Orthodoxy in Massachusetts, 1630–1650* (1959); J. J. Huthmacher, *Massachusetts People and Politics, 1919–1933* (1959); G. L. Haskins, *Law and Authority in Early Massachusetts* (1960). The publications of the various learned societies are important, notably the *Proceedings and Collections* of the Massa-

chusetts Historical Society; the *Proceedings* of the American Antiquarian Society; the *Publications* of the Colonial Society of Massachusetts; and the *Register* of the New England Historical and Genealogical Society. Two co-operative histories are J. H. Lockwood (ed.), *Western Massachusetts*, 4 vol. (1926), and A. B. Hart (ed.), *Commonwealth History of Massachusetts*, 5 vol. (1927–30).

See also *Massachusetts* (1937) in the American Guide Series, prepared by the Federal Writers' Project of WPA. See *League of Women Voters, Massachusetts State Government* (1956); for antiquities, R. P. Bullen, *Excavations in Northeastern Massachusetts* (1949); for genealogy, M. C. Crawford, *Famous Families of Massachusetts*, 2 vol. (1930).

Current statistics on production, employment, industry, etc., may be obtained from the pertinent state departments.

(J. T. A.; L. SL.; R. C. BE.)

MASSACHUSETTS INSTITUTE OF TECHNOLOGY, a U.S. institution of higher education and a research centre, was incorporated in 1861. It opened in Boston in 1865 and moved to Cambridge, Mass., in 1916. See CAMBRIDGE.

MASSAGE is the rubbing, kneading, stroking or tapping of muscles or joints for therapeutic or related reasons.

Massage is one of the oldest forms of therapy. It is mentioned in the earliest medical works, such as those of the Chinese, and at different times has enjoyed great vogue. During the T'ang dynasty (A.D. 618–906) in China, for instance, massage was regarded as one of the branches of the healing art.

In modern medicine, massage is employed only occasionally, usually in those conditions in which an increase in the circulation of blood and lymph is thought to be desirable. Beginning in the 1920s massage was used increasingly in physical therapy. See *PHYSICAL THERAPY: Types of Treatment: Massage*.

MASSASOIT (c. 1580–1661), chief of the Wampanoag Indians, was born in the present limits of Massachusetts about 1580. His tribe of several thousand had been almost destroyed by an epidemic (thought to have been yellow fever) just before the arrival of the Pilgrims on the "Mayflower." In March 1621, an Indian, Samoset, appeared at Plymouth and to the surprise of the Pilgrims spoke to them in English. He arranged for a meeting between his chief, Massasoit, and Gov. John Carver. Massasoit appeared a week later, and signed a treaty of peace with the white men which remained inviolate for 54 years. An aid in the negotiations was the English-speaking Squanto, a surviving member of the Indian tribe which had lived on the site of Plymouth. In 1623, when Massasoit was very ill, Edward Winslow visited him at his principal village, in what is now Rhode Island, and effected a cure. In return for this kindness, Massasoit revealed the plot of a neighbouring tribe to destroy the white men. After Massasoit's death in 1661 his son Metacomet succeeded him and became known as King Philip (see PHILIP, King).

See A. G. Weeks, *Massasoit of the Wampanoags* (1919); William Bradford, *Of Plymouth Plantation 1620–1647* (1952).

MASSAWA (MASSAWAH), in Eritrea province, the largest port of Ethiopia, lies in the Bay of Massawa, on the Red sea, 40 mi. N.E. of Asmara. Pop. (1956 est.) 26,627. It stands on two connected islands, Taulud and Massawa, and on the mainland. Massawa Island is the port and trading centre, Taulud the residential sector; the mainland, hot and arid, has a smaller population. The harbour is well equipped, with shipyards and berths for seagoing vessels; the naval establishments were enlarged after 1960.

Massawa is connected by narrow-gauge railway with Asmara and Agordat. It is served also by a winding mountain road and has an air connection. Industries include saltworks, fishing and marine undertakings (including pearl fishing), bone meal and glue factories. Dried fish and shells are exported. Ethiopian maritime and naval services are being built up at the port, which is administered by the central government.

Christopher da Gama landed with a small force at Massawa in 1541 to help the Ethiopians repel the conquering Muslim invaders. The Turks occupied the island in 1557, and it remained intermittently in Turkish hands for more than 300 years. In 1865 the Turks transferred the port to Egypt; 20 years later it was occupied by an Italian force and the Egyptians withdrew. Massawa (Italian Massaua) was the capital of the Italian colony of Eritrea until 1900, when the government moved to Asmara. It

was the principal base from which the Italians invaded Ethiopia in 1935. Captured by British forces in 1941, it remained under British administration, with the rest of Eritrea, until the federation of Eritrea with Ethiopia in 1952. Eritrea became a province of Ethiopia in Nov. 1962. (F. E. Sp.)

MASSÉNA, ANDRÉ, DUC DE RIVOLI and PRINCE D'ESSLING (1758–1817), French general of the Revolutionary Wars and one of the first of Napoleon's marshals, was born at Nice on May 6, 1758. After going to sea as a ship's boy in 1771 he enlisted in the Royal Italian regiment in the service of France in 1775. In 1789, at the outbreak of the French Revolution, he was a sergeant, married to a surgeon's daughter and settled in some comfort at Antibes. He was soon picked from the volunteers of Var to be "captain of guides" to the new "army of Italy" at Nice; but as early as Feb. 1793 he was denounced by J. M. Collot d'Herbois, the *représentant en mission*, for looting the villages. Spared because his knowledge of the villages and valleys was useful, he was made a general of division in December. Three months later he commanded 20,000 men, in unexpected charge of the offensive which brought the army to the head of the valleys leading down to the Po.

By 1796 he was an experienced wing commander with a genius for moving his men over difficult country in small-scale actions. By 1797 he was Napoleon Bonaparte's most trusted lieutenant, and the regiments under him were famous. He and his men showed immense energy Jan. 11–16, 1797, in the battle of Rivoli; and his conduct in March, crowned by the capture of Tarvisio on the road to Vienna, showed that he could act without being directed by Bonaparte.

Peace, and the political occupation of dependent republics, did not suit Masséna. His rapacity was notorious, and when he went to Paris for the first time he was found to have no political ability. After marked delay he was sent to Italy as L. A. Berthier's subordinate. A week after his arrival at Rome, in Feb. 1798, his men mutinied and expelled him; they had been left without pay, and he had enriched himself. He went home to Antibes and was not taken by Napoleon to Egypt.

In Nov. 1798, however, he was J. B. Jourdan's subordinate, with a corps in Switzerland; and when Jourdan was defeated in March 1799 the command of the whole army passed inevitably to Masséna. In the stubborn withdrawal he was left with 52,000 men, the larger part of the army, facing Zürich and the more numerous Russians and Austrians. The allies prepared their attack, but Masséna attacked first. His battle of Zürich (Sept. 25) was a victory carefully planned in advance, and he followed it by turning aside from Italy A. V. Suvorov's Russian army as it came down from the Alpine passes. He had saved France from invasion and had ended the crisis of 1799. (See FRENCH REVOLUTIONARY WARS.)

Immediately after the *coup d'état* of Brumaire (Nov. 1799) Bonaparte sent Masséna to command the broken army of Italy. The restoration of its fighting spirit was one of Masséna's great achievements, but his vigorous actions in the hills ended in his being besieged in Genoa. Bonaparte then left him to his fate and used the siege as cover for his own Marengo campaign, which on June 14, 1800, reversed the effect of Masséna's capitulation.

Masséna did not love Napoleon's imperial regime, though he was made a marshal in 1804. In 1805 it was only at the last moment that he was sent to command in Italy, where he conducted a sterile campaign on the Adige; he was not ready to fight hard to settle Joseph Bonaparte on the throne of Naples or to win a kingdom for Eugène de Beauharnais. In 1806, however, in unexpected command of the army of Naples, he once more displayed his energy when he had to reconquer Calabria after the British victory at Maida. This episode ended with a demand from Napoleon for the refund of 3,000,000 francs which Masséna had levied. Summoned to Poland, Masséna had a corps in reserve there for four months in 1807.

Masséna was made duc de Rivoli in 1808. He also lost an eye in a shooting accident. He seemed to take little interest in his corps command in the Austrian war of 1809, but in the battles of Aspern-Essling and Wagram he led his men with a fierce heroism

which impressed the whole army: at Wagram he drove round in his carriage, as he had been injured by a fall. Napoleon made him prince d'Essling in Jan. 1810. (See NAPOLEONIC WARS.)

Ignoring the visible deterioration of Masséna's health, Napoleon sent him to Spain in April 1810 to command the army of Portugal. This was the end of Masséna's career. He quarreled with his subordinates, could not cope with the difficulties of supply, fought an unnecessary battle at Bussaco and was baffled by Wellington's lines at Torres Vedras. When he had to retreat from Portugal in March 1811 he attempted to disguise the fact by an impossible march to the south; and when at last he counterattacked, at Fuentes d'Oñoro in May, he could not resolve to press the battle to a decision. He was superseded by Marmont in a humiliating manner; yet the campaign had been marked by a certain fierce obstinacy which helped his fame to survive. (See PENINSULAR WAR.) Masséna was in Paris in 1815 but did not take an active part in the Hundred Days. He died in Paris on April 4, 1817. (I. D. E.)

MASSENET, JULES ÉMILE FRÉDÉRIC (1842–1912), French composer and teacher who helped establish the late 19th-century style of French opera, was born at Montaud, near St. Étienne, on May 12, 1842. He entered the Paris conservatoire in 1853, studying the piano with Adolphe Laurent and composition with Ambroise Thomas. His knowledge of instrumentation was partly acquired from his practical experience as a timpanist in the orchestra of the Théâtre Lyrique. He won the Prix de Rome in 1863, and after traveling to Germany and Hungary he married his piano pupil, Mlle de Sainte Marie, to whom he had been introduced by Liszt.

With the production of *La Grand' Tante* (1867) he embarked on a career as a composer of operas and incidental music. The latter includes the score for Leconte de Lisle's *Les Erinnyes* (1873), containing his song "Élégie." In the same year his "sacred drama" *Marie Magdeleine*, later produced as an opera, established his characteristic style, which made both religious and erotic appeals. *Eve* and *La Vierge* were other choral works of this kind. His opera *Hérodiade* (1881) was followed by his masterpiece *Manon* (Paris, Opéra-Comique 1884), which displayed his gifts for sensuous melody and characterization. Thereafter he remained the principal composer of French opera of his time, admired for his lyrical though often sentimental qualities. His reputation spread beyond France to the extent that he was sometimes described without malice by his detractors as "Mlle Wagner." Among his later operas, produced between 1889 and 1910, are *Esclarmonde* (in which the principal part was taken by Sibel Sanderson), *Werther*, *Thaïs*, *Le Jongleur de Notre Dame* and *Don Quichotte*.

He was an influential teacher of composition; his pupils at the Paris conservatoire, where he taught from 1878 to 1896, included Alfred Bruneau, Gabriel Pierné, Florent Schmitt and Charles Koechlin. Though Massenet achieved great popularity in his lifetime and was sufficiently affluent to spend the latter part of his life at his château at Egreville, his reputation declined in the following generation. He died in Paris on Aug. 13, 1912.

See L. Schneider, *Massenet* (1926); J. Massenet, *My Recollections*, (E. La.) Eng. trans. by H. Villiers Barnett (1919).

MASSEY, WILLIAM FERGUSON (1856–1925), New Zealand statesman, prime minister from 1912 to 1925, was born on March 26, 1856, at Limavady, Ire. While he was at school his father, a tenant farmer, emigrated to New Zealand, buying land near Auckland, and William arrived there in Dec. 1870. He entered parliament in 1894 as a farmers' man, first for Waitemata, then (1896–1925) for Franklin. He became leader of the opposition in 1903, and led the new Reform party to victory in 1912 (see NEW ZEALAND: History).

Always a firm freeholder, Massey enabled crown tenants to convert to freehold more easily, which increased land speculation. He placed the civil service under a nonpolitical Public Service commission, which improved administration. In labour disputes he was very firm; a miners' strike at Waihi in 1912 was ended with some violence and imprisonings; and in 1913, when a strike at the Wellington wharves spread to other ports, militant farmers loaded

and worked ships and served as mounted police. These measures hardened the core of the emerging Labour party and strengthened its appeal. A devoted imperialist opposed to separate sovereign status for the dominions, Massey supported Britain wholeheartedly in World War I. When the 1914 election gave him an uncertain majority, he formed a National government with Sir Joseph Ward's Liberals. After the war, land purchase with borrowed money by returning soldiers led to inflated land prices and large mortgages, which accentuated the postwar fall in prices. To ease this, the Meat board was set up in 1922 and the Dairy board in 1923, while labour became increasingly restive as prices rose. Massey, though a man of limited range, by courage, industry and political astuteness was prime minister with very small majorities for 13 years. He died in Wellington on May 10, 1925. (N. M. TA.)

MASSIF CENTRAL, an upland area in the south-central part of France. It is bordered by the lowlands of Aquitaine and the Loire basin on the west and northwest, and by the valley of the Rhône and Saône rivers on the east and its southern edge overlooks the Mediterranean coastlands of Languedoc. It is conventionally demarcated by the 1,000-ft. contour and in area it occupies about one-sixth of France (32,819 sq.mi.). The highest peak is the Puy de Sancy (6,188 ft.), while to the south of this lies the Plomb du Cantal (6,096 ft.). The greater part of the massif, however, consists of plateaus lying between 2,000 and 3,000 ft.

About three-quarters of the region is underlain by crystalline

was characterized by volcanic activity, continuing into the early Quaternary period and giving rise to the great volcanic cones and lava plateaus of Auvergne, Velay, etc. All the volcanoes are now extinct.

For long periods of geological time much of the massif was exposed to denudation; this resulted in the formation of extensive plateaus at various altitudes. The older of these are now deeply dissected by river valleys. The highest parts of the massif have also been glaciated; small cirques and moraines occur in Mt. Dore and in the Cantal.

In the Massif Central are the sources of several of the larger French rivers: the Loire and the Allier rise in Auvergne; the Cher, Creuse and Vienne originate in Limousin; the Dordogne, Lot and Tarn flow westward into Aquitaine; and numerous smaller rivers in the east contribute to the Rhône-Saône drainage.

Physiographic Regions.—The diversity of geological structure is reflected in the variety of regions found within the massif. Four broad divisions can be recognized.

The Eastern Margins overlook the Rhône-Saône trough and Languedoc in a marked fault-line scarp and consist mainly of crystalline uplands. Morvan in the north reaches 2,959 ft.; southward, in order, lie the divisions of Autunois, Charolais (the lowest part of the eastern margins, averaging only 1,500 ft.), Beaujolais (up to 3,320 ft.), Lyonnais and Vivarais (4,705 ft.). The last two are separated by the St. Étienne depression. The Cévennes continue the region southward from Vivarais; their eastern scarp face is intensely dissected and they rise to the granite summits of Mt. Aigoual (5,141 ft.) and Mt. Lozère (5,584 ft.). Heath and moorland occupy the higher parts of the eastern margins and the scenery at such elevations is characterized by bleakness. Snow often lies for several months of the year. At lower levels, especially in Morvan and the Cévennes, considerable areas are forested. The natural forest of beech, oak and chestnut has been greatly depleted by clearing, but more recently there has been extensive development of state forests, mainly of the conifers. On the slopes of the Cévennes below 1,500 ft., Mediterranean scrub forest occurs, with mulberries and olives planted on the lowest parts.

The emphasis in farming throughout the whole region is pastoral; cattle are especially important in Charolais and Lyonnais, reared for both meat and milk. In the Cévennes, sheep are dominant and large numbers move up to the higher pastures from Languedoc in the summer. Vineyards and orchards are found on the lower eastern slopes from Charolais southward; the orchards produce peaches, apricots, plums and cherries, and the vineyards of Beaujolais and Charolais are the source of many of the famous Burgundy wines.

The Western Margins bordering the Aquitaine lowlands include Limousin in the north where a plateau bevels the crystalline rocks at 1,500–2,500 ft., but rises to 3,209 ft. in the Millevaches plateau. Rough grassland and heath are extensive on the exposed plateaus and the relatively high rainfall coupled with the impermeable bedrock is responsible for the frequent occurrence of peat bogs and pools of water. Sheep and hill cattle are kept on the poorer areas, while the more favoured parts support increasing numbers of the famous Limousin cattle which are bred for beef and veal. In the southwest of the massif lies Ségala, another crystalline plateau similar in elevation to Limousin and named after rye (*seigle*) which was formerly its main crop. The Montagne Noire and the Monts de Lacaune, projecting from the southwest of the massif, are prominent crystalline massifs rising to almost 4,000 ft.

Arable farming in the western margins is limited by low temperatures on the uplands and by poor soils on the crystalline rocks, though liming and fertilizing have in places made great improvements (e.g., in Ségala). Wheat, potatoes and fodder crops are generally the main products.

The Central Region consists mainly of Auvergne and has a greater diversity of scenery than the other regions. Three basic types of structure can be recognized: first, the crystalline massifs, such as Forez, Livradois and Margeride (up to 5,098 ft.); secondly, the volcanic regions of Les Puys (a chain of recent ash or lava cones, culminating in the Puy-de-Dôme, 4,806 ft.), Mt. Dore and Cantal (large volcanic cones, originally comparable in size

MAP SHOWING REGIONS OF MASSIF CENTRAL, FRANCE AND ITS ADJACENT AREAS

rocks, mainly granite, gneiss and schist. The structures found in this basement were produced by the Hercynian earth movements, and in this respect the massif may be compared with certain other European regions, e.g., Brittany or the Vosges. Resting on the crystalline basement in some areas are sedimentary deposits of a later age, such as the Jurassic limestones of the Causses or the Tertiary sands and clays of the upper Allier and Loire valleys. One of the most recent episodes of geological history in the massif

with Vesuvius and Etna respectively, but greatly dissected by subsequent erosion), Céallier and Aubrac (basaltic plateaus rising to over 4,500 ft.), and Velay (consisting of lava plateaus flanking the basin of Le Puy with its striking volcanic hills); thirdly, the downfaulted Tertiary basins of Limagne, the Forez plain and Roannais.

These variations in relief and geology are among the factors responsible for the different types of land use in Auvergne. Rough pasture and moorland occupy the high ground; forest is not usually found above 4,000 ft., though it is extensive at lower levels in many areas. Considerable numbers of cattle are kept, mainly for dairy produce, and full use is made of the higher mountain pastures in summer. Many distinctive cheeses, such as Cantal and St. Nectaire, are produced in Auvergne. There is also much arable farming in the valleys; wheat, barley, oats, potatoes and sugar beet are important crops and market gardening is practised near the large towns. Vineyards and orchards occupy favoured slopes, particularly around the basins of Forez and Limagne.

The *Limestone Regions* principally in the south of the massif have distinctive characteristics associated with the permeability of the limestone and the resultant general lack of surface moisture and drainage. The largest of the limestone regions is the Grands Causses, where the Jurassic limestones are beveled by extensive peneplained surfaces at 2,500–3,500 ft. On these uplands, the scenery is unattractive, with scanty vegetation, except for some recent forest plantations. The area is, however, trenched by the imposing gorges of the Tarn, Lot and their tributaries, in some places up to 2,000 ft. in depth. The Tarn and Lot rise outside of the limestone region and maintain a continuous flow of water, though the volume is much reduced in summer.

The main economic importance of the Causses lies in the sweet but scanty pasture on the limestone plateaus, which supports fair numbers of sheep and some cattle. Roquefort cheese, made from ewes' milk, is a well-known product of the region. Arable farming is confined to depressions in the plateau surface where some soil has collected. Small orchards and vineyards are found on south facing slopes within the deep gorges.

Mining and Industry.—Coal is the most important mineral produced in the massif, but the deposits are comparatively small and scattered since only restricted patches of Carboniferous rocks have survived subsequent periods of erosion. The coal fields at St. Étienne, Alès and Blanzay each produce between 2,500,000 and 3,500,000 tons a year. Small-scale mining of metal ores is associated with the crystalline rocks, such as lead and hematite in the Cévennes, zinc (refined at Viviez) in Ségalas and pyrites in Lyonnais. At St. Yrieix, south of Limoges, there are china clay deposits worked since 1755.

The coal fields have given rise to important steelworks, now using pig iron from Lorraine. The development of steelworks in the massif has been helped by strategic considerations, the sites selected being less vulnerable than those near France's north-eastern frontiers. Manufacture of armaments, locomotives, machinery and other metal goods is carried on in the St. Étienne region, at Le Creusot and Montluçon. The second most important industry is that of rubber, established by Michelin at Clermont-Ferrand and employing about 18,000 workers. A smaller Dunlop rubber factory is located at Montluçon. At Limoges, the porcelain industry has long been famous for its fine products. Various textile industries are widespread in the massif: those connected with silk and rayon are of considerable importance in towns within 30 mi. of Lyons (including St. Étienne) and at Roanne. Other industries are concerned with the manufacturing of bricks and tiles, furniture, paper, leather goods, glass, lace, etc., often using local raw materials.

Electricity for industry and other consumers comes both from thermal power stations and from hydroelectric installations. In the 1960s about one-third of France's hydroelectricity was generated in the massif, mainly from large plants on the Dordogne, Cère, Truyère, Lot and Tarn, whose gorgelike valleys provide ideal dam sites. Problems of seasonal variation in river discharge have been partially overcome by the construction of barrages in series.

Population.—The population is unevenly distributed over the massif. The largest conurbation is centred around St. Étienne; this area as a whole containing about 300,000; Clermont-Ferrand and Limoges come next in size. In contrast, there are areas which are virtually uninhabited including some plateaus over 3,000 ft and parts of the Causses. Lozère has the lowest population of any *département* in France. The more agriculturally productive areas possess a more dispersed population and numerous market towns. There are also tourist centres, such as Vichy, La Bourboule and Royat.

MASSILLON, JEAN BAPTISTE (1663–1742), bishop of Clermont, one of the great preachers at the court of Versailles was born at Hyères in Provence on June 24, 1663. Educated by the Oratorians at Hyères and Marseilles, he joined the order in 1681. He was ordained in 1691 and in 1696 made director of the St. Magloire seminary in Paris. But his heart was in preaching and his sermons at the Paris oratory led to his preaching at court. After hearing him, Louis XIV said that formerly he had been well pleased with preachers, but now he was ill-pleased with himself. "On the fewness of the elect" is considered his best sermon, but the most striking words he ever pronounced were the first of his funeral oration of the Roi Soleil. *Dieu seul est grand*. As a preacher he spoke to the heart, and while severe in teaching was gentle in his treatment of sinners. Appointed bishop of Clermont in 1719, he proved himself a zealous and enlightened prelate who did much for the poor, gaining relief for them from onerous taxes. He died at Beauregard near Clermont on Sept. 18, 1742.

See *Oeuvres complètes*, ed. by E. A. Blampignon, 3 vol. (1865–86); see also A. A. L. Panthe, *Massillon* (1908). (M. DE LA B.)

MASSILLON, a city of Stark county, eastern Ohio, U.S., on the Tuscarawas river, 8 mi. W. of Canton. It is an important manufacturing centre, its principal products being electric furnace alloy steels, stainless steels, cold-drawn steels, evaporators, household wares, surgeons' rubber gloves, lock washers and automobile parts. It is also a major centre for the production of mass advertising materials.

Massillon was founded in 1826 with the advent of the Ohio and Erie canal and became the greatest "wheat city" of the state. It was incorporated as a city of second class in 1853 and as a city of first class in 1868. The public library, housed since 1914 in a structure of modified Georgian design, is connected architecturally and administratively with the Massillon museum, which occupies the oldest building in Massillon, the remodeled residence of James Duncan, founder of the city. The city was named after Bishop Jean Baptiste Massillon of France. A state hospital for the insane is located there.

For comparative population figures see table in OHIO: Population. (E. T. H.)

MASSIMO (MASSIMI), a Roman princely family of great antiquity. Though their reputed descent from the Maximus of republican Rome is purely legendary, they may be traced back with some confidence at least to the end of the 10th century A.D. Their name recurs in the annals of medieval Rome, but they did not rise to particular wealth or importance before the 15th–16th centuries. The Palazzo Massimo, one of the finest Renaissance buildings in Rome, was built by Baldassare Peruzzi for Pietro di Domenico Massimo (d. 1544) on the ruins of a far older family palace, in which the first Roman printing press had been established by immigrant Germans in 1467 and which had suffered destruction during the sack of Rome in 1527. The sons of Pietro's brother ANGELO (d. 1550) founded four branches of the family. Two of these became extinct in the 17th century. The Massimo delle Colonne, however, descended from Angelo's son FABRIZIO (d. 1633), became lords of Arsoli in 1574 and princes of Arsoli in 1826, with the rank of Roman prince for all members of the

branch; and the Massimi d'Aracoeli (extinct in 1907), descended from TIBERIO (d. 1588), received the Roman duchy of Rignano in 1828.

MASSINE, LEONIDE (1896–), Russian dancer and choreographer noted for the wit and style of his characterizations. was born in Moscow on Aug. 9, 1896. He developed the symphonic ballet, as in *Les Présages* (Tchaikovsky's Fifth) and *Choreartium* (Brahms's Fourth), and excelled in staging light, sparkling ballets such as *Gaîté Parisienne* and *Le Beau Danube*. Massine graduated from the Imperial Ballet school, but had almost decided to renounce dancing for acting when Sergei Diaghilev, seeking a replacement for Vaslav Nijinsky, whom he had just dismissed, invited him to join his company. After further training under Enrico Cecchetti, Massine made his debut in *La Légende de Joseph* in 1914. Diaghilev supervised Massine's artistic education, taking him to museums and concerts, and encouraged his choreographic talent. His first ballet was *Le Soleil de Nuit* (1915). For the Diaghilev company he created such masterpieces as *Le Tricorne* and *La Boutique Fantasque*.

From 1932 to 1938, Massine was principal dancer and choreographer of the Ballet Russe de Monte Carlo. Disagreements with its director, Col. Wassily de Basil, led Massine to resign and form the new Ballet Russe de Monte Carlo, which he headed until 1942. Later he appeared with the American Ballet Theatre and the Royal Ballet of England. In 1960 he produced *Commedia Umana*, a ballet version of Boccaccio's *Decameron*, for the Nervi festival, in Italy. (LN. ME.)

MASSINGER, PHILIP (1583–1640), English Jacobean and Caroline playwright whose gifts for comedy, plot construction and social realism are seen at their best in his most successful play, *A New Way to Pay Old Debts*. He was baptized at St. Thomas', Salisbury, on Nov. 24, 1583, the son of Arthur Massinger (thrice member of parliament and fellow of Merton college, Oxford), a gentleman in the service of the earls of Pembroke at Wilton house. Massinger matriculated at St. Alban hall, Oxford, in 1602 but there is no evidence that he graduated. Nothing is known for certain about his life from 1602 to 1613, though he may have been an actor. After an indefinite period of apprenticeship, during parts of which he was writing for the theatrical manager Philip Henslowe and collaborating, from c. 1613, with John Fletcher and others, he began as an independent dramatist c. 1620.

When Fletcher died in 1625, Massinger succeeded him as the regular dramatist of the King's Men. His plays were not so successful as Fletcher's; there is much evidence in his dedications that he was poor and no certainty that he ever had a regular patron. Apart from guesses based on the play texts and their dedications, personal details about him are very scanty: no record of a marriage has been found; the idea (first suggested by W. Gifford [see *Bibliography*] because of certain features of the plays) that he became a Roman Catholic has not won acceptance. Anthony à Wood in *Athenae Oxonienses* (1691–92) says that he died suddenly at his house near the Globe theatre and was buried, according to his friend Sir Aston Cockayne, in Fletcher's grave at St. Saviour's, Southwark, on March 18, 1640.

The Canon.—For Massinger's share in the Beaumont and Fletcher canon, see BEAUMONT AND FLETCHER. Two other important plays written in collaboration are *The Fatal Dowry* (1616–19, with Nathan Field, *q.v.*), a domestic tragedy in a French setting which was the basis of Nicholas Rowe's *Fair Penitent* (1703), and *The Virgin Martyr* (1620? with Thomas Dekker, *q.v.*) about the persecution of Christians under Diocletian, with elaborate scenes of torture, conversion and apotheosis. Fifteen of Massinger's unaided plays have survived, many of the dates of which can only be conjectural. There are four tragedies: *The Duke of Milan* (1621–22), *The Unnatural Combat* (1624?), *The Roman Actor* (1626), *Believe as You List* (1631); seven tragicomedies: *The Maid of Honour* (1621?), *The Bondman* (1623), *The Renegado* (1624), *The Parliament of Love* (1624), *The Picture* (1629), *The Emperor of the East* (1631?), *The Bashful Lover* (1636); and four comedies: *A New Way to Pay Old Debts* (1621 or 1622), *The Great Duke of Florence* (1627?), *The City Madam* (1632?), *The Guardian* (1633).

The Plays.—Of the tragedies, *The Duke of Milan* and *The Unnatural Combat* are both skillfully told mystery stories of a horrific and melodramatic sort, Fletcherian in style and not showing much of Massinger's individuality. *The Roman Actor* and *Believe as You List*, historical tragedies in a classical setting, are very different. *The Roman Actor*, "the most perfect birth of my Minerva," is perhaps his best serious play. It is the story of the actor Paris and Domitia, wife of the emperor Domitian, and is skillfully constructed to provide a defense of the stage in the scene depicting Paris before the Roman senate (act i, scene 3). Also, in the character of Paris, Massinger draws a sympathetic and truthful portrait of a great actor. Both this play and *Believe as You List* give scope for Massinger's fondness for long trial scenes, of which the one in *Believe as You List* (Antiochus before the Carthaginian senate, act ii, scene 2) is exceptionally studied: the struggle between the tempted and persecuted pretender Antiochus—beggar, suppliant, galley slave, but marked, it seems, by innate royalty—and his great enemy the Roman general Flaminus, gives unity to the play and is handled freshly, and with genuine historical sense, in a way much surpassing Fletcher's treatment of similar stories.

Four of the tragicomedies may be selected as representative. The chief interest of *The Bondman*, a play about a slave revolt in Syracuse led by a Theban nobleman in disguise, is its reflection of Massinger's independent-minded concern with state affairs, and his ability to relate them to contemporary situations. *The Renegado*, with its heroic Jesuit, religious sentiment and conversion scenes, and its skill in rendering locality (e.g., the Tunis bazaar, act i, scene 3), is one of the plays which gave rise to the theory that its author became a Roman Catholic. *The Maid of Honour*, which M. Chelli in *Le Drama de Massinger* (1924), considered the most complete expression of Massinger's talents, combines some political realism with the high-souled courtly refinement that came to dominate Caroline drama through the influence of such courtly amateur playwrights as William Cartwright and Thomas Killigrew. Of this refinement Massinger's last play, *The Bashful Lover*, is a fairly exact expression. Lastly, *The Picture*, despite its interesting feminine roles and its well-managed but artificial story, may justly be considered a "decadent" play because it treats morality as a branch of etiquette.

The tendency of the serious plays to conform more and more to the high-flown sentiments of Caroline fashion is contradicted by the mordant realism and satirical force of Massinger's two great citizen comedies. *A New Way to Pay Old Debts* is the best thing of its kind outside Ben Jonson, to whose plays it is much indebted. It also draws inspiration from Thomas Middleton's *A Trick to Catch the Old One* (1608). Through the grim and powerful figure of Sir Giles Overreach, the "cormorant" extortioner, and his suborned man of law Mr. Justice Greedy (based on two actual personages, Sir Giles Mompesson and Sir Francis Michell, whose financial swindles had been exposed in 1621) Massinger expresses genuine indignation at economic oppression and social disorder. *The City Madam* deals with similar evils, within a more starkly contrived plot curiously combining naturalistic and symbolic modes in its story and characterization. The gradual revelation of the character of the merciless miser, Luke Frugal, is splendidly handled, and Luke is made the satirical scourge of the superstition, affected gentility and wealthy ostentation of city ladies. These two comedies, with the Roman tragedies, put Massinger in a class above Fletcher, with whom he otherwise has much in common.

Though fond of relying on devices such as the trial scene, sudden changes of character and the concealment of secrets from the audience, Massinger was an exceedingly competent dramatic craftsman both as a storyteller and as a composer of even-paced and vigorous verse. He originated little and diluted much that he inherited from Shakespeare and his other predecessors, but he often appears much less remote from the real world of his day than the other dramatists of the 1620s and 1630s.

Reputation.—A few of Massinger's plays were revived after the Restoration; Samuel Pepys enjoyed *The Virgin Martyr* and *The Bondman* (with Thomas Betterton), and Betterton revived

The Roman Actor. From David Garrick's revival of 1748 until about 1880 *A New Way to Pay Old Debts* held the stage in Great Britain and the United States, with Charles Kemble, George Cooke, Edmund Kean, the Booths and others creating a remarkable tradition in the character of Sir Giles Overreach. There were collected editions by T. Coxeter (1759 and 1761), Monck Mason (1779, with an essay by T. Davies lamenting the current neglect of Massinger), W. Gifford (1805, 1813, reprinted by F. Cunningham, 1871) and Hartley Coleridge (1839-40). S. T. Coleridge praised Massinger's narration and verse ("the nearest approach to the language of real life at all compatible with a fixed metre") but not his characterization. Charles Lamb, in *Specimens of English Dramatic Poets* (1808), rated him low: "he never shakes . . . the mind with grief." Notable Victorian critiques include S. R. Gardiner's article on the political elements in the *Contemporary Review* (Aug. 1876); L. Stephen's destructive analysis in *Hours in a Library*, vol. ii (1877); and Swinburne's enthusiastic essay in the *Fortnightly Review* (July 1889). The book by A. H. Cruickshank (1920), reviewed by T. S. Eliot in a well-known essay in *The Sacred Wood* (1920), proved a starting-point for modern criticism, which stresses Massinger's realism, satirical power, political and social attitudes and his share of the responsibility for the "decadence" of the drama.

MASSINGHAM, HENRY WILLIAM (1860-1924), British journalist, known for his advanced and often unpopular liberal opinions, was born at Old Catton, Norfolk, on May 25, 1860. Educated at King Edward VI's school, Norwich, he started as a reporter at the age of 17 and after working on various newspapers, including four years as editor of the London *Daily Chronicle*, was appointed editor of the *Nation* in 1907, a post that he held until his resignation in 1923. One of the best all-round journalists of his day, he was a trenchant writer on politics and did not hesitate to express unpopular views, such as his opposition to the South African War and criticism of the peace treaty of 1919. Although he ultimately joined the Labour party, his sympathies were with the ethics rather than the economics of socialism. He was also a discerning critic of literature and drama. He died at Tintagel, Cornwall, on Aug. 28, 1924.

See H. W. M.: a *Selection from the Writings of H. W. Massingham*, ed. by H. J. Massingham (1925), which contains tributes by Bernard Shaw and other associates.

MASSON, FRÉDÉRIC (1847-1923), French historian and academician, best known for his books on Napoleon, was born in Paris on March 8, 1847. In *Napoléon inconnu* (1895), Masson, with Guido Biagi, brought out the unpublished writings (1786-93) of the future emperor; these were notes, extracts from historical, philosophical and literary books and personal reflections.

His other works include several books on Josephine; *Napoléon et sa famille*, 13 vol. (1897-1919); *Napoléon et son fils* (1904); and *Autour de Sainte-Hélène*, 3 vol. (1908-12). Masson died in Paris on Feb. 19, 1923.

A bibliography of his works, including anonymous ones and those under an assumed name, was published by G. Vicaire, *Manuel de l'amateur des livres du XIX^e siècle*, vol. v (1904).

MASS PRODUCTION. The term mass production refers primarily to methods of organizing manufacturing processes to attain high output rates. Both mechanization of production processes—the substitution of machine operations for manual work—and application of appropriate systems of industrial administration are involved. Although some of the more striking examples of mass production are provided by giant enterprises, high output production techniques are not restricted to large industrial organizations. The essential features of mass production are: (1) manu-

facture of standardized commodities; (2) long production runs; (3) continuous plant operation; (4) use of specialized production and material-handling equipment; (5) plant arrangements minimizing material handling and based on the particular sequence of operations required for the production of the standardized product; (6) division of labour to the point where most production workers perform short and simplified operation sequences repetitively; and (7) systematic planning, direction and control of manufacturing operations. When these characteristics are present, output per time period and per worker are both high, compared with the output rates obtained by small-lot, custom production in plants having nonsequential layouts and little specialization of jobs and equipment.

EVOLUTION OF MASS PRODUCTION

Mass-production methods were not applied on a wide scale in the U.S. until the beginning of the 20th century but their origins are much older. Factory production with considerable division of labour existed in western Europe long before the general employment of powered equipment for manufacturing processes which began with the industrial revolution of the 18th and 19th centuries. There are even accounts of manufacturing methods as early as the 13th century which indicate that arrangements much like the assembly line of the 20th century were then used for outfitting ships and making weapons. (See INDUSTRIAL REVOLUTION.)

Several streams of technical, managerial and social development culminated in modern mass production. Expansion of basic scientific knowledge and improvement of technology opened up new possibilities for invention and innovation in production, including new and improved materials, more efficient manufacturing processes, and equipment designed to operate faster and more accurately and last longer. The rise to dominance of the corporate form of enterprise allowed aggregation of large amounts of capital in continuous and stable organizations able to conduct long-term programs of product and process development. Beginning with the scientific management movement of the early 20th century, industrial management increasingly emphasized elimination of waste and promotion of efficiency. Many of the most modern analytical tools available to managers—time and motion study, job analysis, budgeting and cost accounting, equipment selection and replacement study, production planning and scheduling—are basically refinements of those used or suggested by the pioneers of scientific management. (See MANAGEMENT SCIENCES.) The philosophy of mass production which emerged as managerial and technical proficiency increased is that output expansion, quality improvement and cost reduction achieved through improvement of methods and investment in plant and equipment should be major goals of industrial enterprise. In mass-production economies which give expression to this philosophy, wage rates and living standards tend to rise in step with productivity increases so that expansion of output tends to be cumulative.

Clearly, mass production is as much a market phenomenon as anything else, for it implies mass consumption. Urbanization, widening of educational opportunity, reduction of inequalities in income distribution, social and geographical mobility of the population and other influences which induce homogeneity in tastes and patterns of consumption both impel mass production for mass markets and are furthered by it. As individual manufacturing firms concentrated on large-scale production, a system of industrial specialization evolved, in which firms may mass produce and sell in industrial markets one or a few items used, in turn, as materials or components by other producers whose products ultimately find their way to consumers.

PLANNING FOR MASS PRODUCTION

In any variety of production a certain amount of planning necessarily precedes conduct of operations. Time and effort must be devoted to determination of product characteristics, quantity of output, production methods, equipment to be employed and other aspects of the manufacturing process before work can begin. Thorough, often elaborate, planning must be completed in advance of mass-production operations and it is the high ratio of long-range

planning to planning for day-to-day operation which sharply differentiates representative mass-production enterprises from other types. Manufacturing establishments which produce mainly to customers' orders often shift much of the burden of product conception and design to the buyer.

Similarly, small-lot producers escape inventory expense at the cost of convenience to purchasers of their products. Mass-production enterprises, in contrast, must anticipate the future flow of orders and often must produce to build up inventories. The flexibility of general-purpose equipment which permits quick production shifts must be sacrificed in large part for the efficiency which comes from use of special-purpose equipment. Because of the large investments which must be made in plant and equipment and because of the often lengthy intervals from the decision to proceed with product development and plant construction to the attainment of expected rates of production and to repayment of plant and equipment costs, a potentially high and stable demand, permitting long production runs without major changes in products, generally is regarded as necessary. Continuous and intensive use of plant for reduction of fixed cost per unit of output requires that pronounced seasonal fluctuations or other variations in demand be at a minimum. The market risks in equipping for mass production of new products obviously are great. Even conversion to high-volume methods for established products is not without risk.

Standardization of products, materials, processes, equipment and other factors of production is as integral a part of mass production as interchangeability of product components is a key requirement for specialization of operations. The degree to which production processes can be broken down to simple operations which workers can perform with increased speed and accuracy is determined by the final effect on total production time. Hand fitting, rework and repair of product components and multiple inspections must be eliminated as far as possible if gains from division of labour and mechanization are not to be offset. Elimination of needless product variety, reduction of the total number of individual parts that must be made in order to turn out a series of product sizes, maximum utilization of specialized and expensive equipment units, minimization of material and parts inventories and avoidance of repetitive design and manufacture of items that differ only slightly are but a few of the advantages which stem from well-conceived company, industry and national programs of industrial standardization.

Proper standards for dimensions and other properties of materials and parts are the basis for sampling inspection and statistical control of quality, measures which can contribute to cost reduction in mass manufacture. Standardization, however, must be planned carefully in co-ordination with every other plan of production to assure that standards for products and processes are neither premature, overly rigid nor excessively narrow.

The visible results of the comprehensive planning for mass-production operations are production and assembly lines, combinations of work stations, machines and material-handling equipment arranged for continuous flow of units from raw material to finished product. In designing a production line, the sequences of operations for manufacture of each product component are determined, man-machine combinations for each manufacturing step are provisionally decided and plans or models of proposed physical arrangements are prepared for study. Each movement of material is scrutinized in detail, simplified or shortened if possible and crossflows and backtracking eliminated. Operations are balanced by so setting work assignments, numbers of machines and operating rates that all stations along the line have the same production rate. Where their use is indicated, mechanical or gravity conveyors are selected to couple the work stations. Auxiliary departments and plant services are planned in conjunction with the production layout to maximize convenience and ease of maintenance. The end in view is a set of production facilities capable of performing as an integrated unit with no bottlenecks and with minimum flow times and distances.

Operation of an automobile assembly line epitomizes mass production. Starting with a bare chassis, components are attached successively as the growing assemblage moves along the conveyor.

Feeder lines on which parts are matched into subassemblies intersect the main line to deliver body parts, running gear, engines and other assemblies. Each worker along the line performs his job as the units move past, and each part and tool is delivered to its point of use in exact synchronization with the line. An intricate system of production scheduling and control ensures that the right body type and colour, trim, engine and optional equipment arrive together for assembly, for a number of individual assembly combinations are on the line simultaneously. The automobiles driven off the end of the line under their own power consist of parts which a few weeks before were raw materials, a few days before were unfinished in a distant supplier's plant and only a few minutes before were starting down the line.

In the most modern automobile plants, as has been true in such continuous process industries as petroleum refining and chemical manufacture for some time, many of the production lines are almost completely mechanized and workerless, consisting almost entirely of automatic, self-regulating equipment. A new word, "automation," was coined to describe the process of making machines to run machines, and the growing technology of automatic control is having a dramatic impact throughout the mass-production industries. As the promise of automation for high and sustained rates of output is made a reality, the terms automation and mass production are likely to be virtually synonymous. See also AUTOMATION and references under "Mass Production" in the Index.

MASS SPECTROSCOPY is that field of physics in which the motion of charged atoms and molecules in electric and magnetic fields is used to sort those atoms and molecules according to their atomic masses. The instruments used for this purpose are mass spectrometers and mass spectrographs, differing only in their method of making the sorted charged particles (ions) observable. In the mass spectrometer, the sorted ions are detected electrically; in the mass spectrograph, they are detected photographically or by other nonelectrical means. The term mass spectroscopy is used in a loose sense to include both types of instrument. A person who specializes in their use is called a mass spectroscopist.

A number of quite different instruments can also sort out atomic masses but do not depend on the motion of ions in electric or magnetic fields. In the 1960s these instruments were also classed as mass spectrometers but with a prefix added; they included the microwave absorption mass spectrometer, the nuclear-induction mass spectrometer, the molecular mass spectrometer and the optical mass spectrometer. They will not be discussed further here, but it should be noted that many of the problems that the mass spectrometer has solved could also be solved through the use of these instruments.

The fundamental problems to which the mass spectroscopy has been applied include identification of the isotopes of the elements; determination of the relative abundances and precise masses of isotopes; energy levels of atoms and of molecules; the structure of molecules; equilibrium and kinetics in chemical reactions; surface chemistry; the study of geological samples and hence the history of the earth; the study of meteorites and hence the history of the solar system; and studies in medicine and biology, generally through the use of isotopic-tracer techniques (see ISOTOPE).

About 1940 the methods of mass spectroscopy were first applied on a large scale to the separation of isotopes. The initial impetus was the need to isolate U^{235} for use in producing atomic energy (q.v.). The techniques were quickly extended to the isotopic separation of other elements.

Mass-spectrometric equipment became available commercially about 1940, and for a number of years was limited to gaseous-state studies, as in the analysis of hydrocarbon mixtures and inorganic gases. The first large-scale use of this equipment was in the on-stream analysis of the gases in isotope separation plants.

In 1943 special purpose mass spectrometers (with helium as a tracer gas) became available for leak detection.

In the early 1960s equipment became commercially available for the analysis of solid materials. It has been applied mainly to the determination of the chemical purity of solid materials, having the advantage (over the usual optical spectroscopic methods) of higher sensitivity to trace impurities.

Historical Mass Spectroscopy.—In 1886 E. Goldstein, experimenting with electrical discharges in gases at low pressures (a neon light is a well-known example), observed that if a hole was placed in the negative electrode, the luminous discharge extended through that hole into the gas behind. He concluded that this luminosity came from some sort of beam that traveled in the opposite direction from that of the then-known cathode rays; by analogy to their method of production, he named them Kanalstrahlen, or canal rays. In 1898 W. Wien showed that these beams could be deflected by magnetic fields. This fundamental property serves as the basis of a large part of mass spectroscopy. An ion beam (homogeneous as to energy or velocity) of small mass is deflected more sharply by the magnetic field than one of larger mass with the same energy or velocity (fig. 1); *i.e.*, the ions are sorted according to mass by deflection in a magnetic field.

A series of investigations was carried out (1907–13) by J. J. Thomson using simultaneous parallel electric and magnetic fields.

FIG. 1.—TRAJECTORIES IN A MAGNETIC FIELD OF TWO PERFECTLY COLLIMATED ION BEAMS HAVING THE SAME ENERGY BUT DIFFERING IN MASS

With this arrangement of fields an ion beam is resolved into a series of more or less complete parabolas, each characteristic of ions of one mass. The limitation of the simple magnetic deflection (*i.e.*, that the energy or velocity of the ions in the beam be constant) is removed. With this instrument Thomson investigated the ions formed by electrical discharges in a number of gases. He renamed the ion streams positive rays since most of the ions he observed had positive charges. Thomson's apparatus could separate ions differing in mass by 1 part in 15. His investigations in 1913 gave the first indication that ordinary neon was a mixture of two kinds of atoms (isotopes) that differed in mass by two atomic mass units.

All the devices noted above are analogous to the pinhole camera in optics; *i.e.*, no focusing is involved and definition of the ion beams is only as good as the pinhole is small. An advance came with the introduction of focusing types of mass-sensitive instruments. The use of ion lenses so improved the resolving power and sensitivity of the devices that by 1920 they had become prac-

FIG. 2.—DIRECTION-FOCUSING ACTION AND MASS SENSITIVITY OF A MAGNETIC FIELD FOR ION BEAMS HOMOGENEOUS AS TO ENERGY

tical tools. In 1918 A. J. Dempster introduced the first of these focusing analyzers. In his analyzer an ion beam (homogeneous as to energy or velocity) diverging from a defining slit was refocused after passing through a magnetic field, different masses being brought to focus at different points (fig. 2). Analogous to the function of a cylindrical lens in optics this is called direction focusing. In 1919 F. W. Aston introduced a focusing analyzer (fig. 3) in which successive electric and magnetic fields were oriented to bring to focus all perfectly collimated ions of one mass, independent of their velocity. This is called velocity focusing. Because the different mass ions were recorded as a spectrum of lines on a photographic plate Aston in 1920 introduced the term mass spectrum and termed the instruments mass spectrographs; these, with some expansion, became the standard designations. With these two types of instrument (which in 1920 could resolve masses that differed by 1 part in 100) the isotopic compositions of many elements were investigated and the first precise measurements of atomic mass were made.

By the mid-1960s instruments based on direction focusing had become standard tools for isotopic-abundance measurements. When designed for high resolving power they could resolve masses differing by 1 part in 5,000, and when designed for high accuracy in relative isotopic-abundance measurement they yielded accuracies of 1 part in 10,000.

In 1935–36 Dempster, K. T. Bainbridge and J. Mattauch introduced instruments using successive electric and magnetic fields; *i.e.*, a configuration similar to fig. 3, but combined to refocus ion beams that are inhomogeneous both in direction and in velocity. This is called double focusing; instruments based on this principle produce much higher resolution than those based only on direction focusing. However, double-focusing instruments are quite com-

FIG. 3.—MASS SPECTROMETER USED BY F. W. ASTON. SLITS S_1 AND S_2 DEFINE AN ION BEAM. THE ELECTROSTATIC DEFLECTION INTRODUCES A VELOCITY DIVERGENCE IN THE ION BEAM WHICH IS JUST CANCELED BY THE MAGNETIC FIELD SO THAT VELOCITY FOCUS OCCURS AT THE PHOTOGRAPHIC ION DETECTOR

plex and are generally used only when simpler instruments are inadequate; e.g., for measuring precise atomic masses and for the chemical analysis of solids. By the mid-1960s double-focusing instruments could separate ions differing in mass by as little as 1 part in 750,000 and could measure relative atomic masses to an accuracy of 1 part in 100,000,000.

All of the methods that have been described involve electric and magnetic fields that are invariant in time. In 1932 W. R. Smythe introduced alternating electric fields at radio frequencies (RF) to separate ions of different mass. Ions with the same energy but different mass have different velocities, the lighter masses moving faster. If a single short pulse of ions is directed into a tube of fixed length, the lighter (faster moving) ions will separate from the heavier (slower moving) ions. At the end of the free-flight path there will be a temporal resolution of the original pulse into separate mass components. In a practical instrument this separation is repeated over and over. A mass-sensitive instrument based on time-dependent phenomena to obtain mass resolution is generally termed a time-of-flight (or RF) mass spectrometer.

A number of simple useful RF mass spectrometers were developed in the 1950s. These included the pulsed-beam instruments, the RF-accelerator instruments, the omegatron and the quadrupole instruments. By the mid-1960s these were used routinely in chemical applications. Since they could be made small and very light, they were used extensively in space science; for example, in determining the composition of gases through which satellites move.

For precise mass determination RF fields alone are inadequate. However, combination of RF techniques with deflection in magnetic fields permits very high resolution and precise determination. Instruments of this type include the omegatron and the mass synchrotron. By the mid-1960s these had achieved resolutions of 1 part in 100,000 and accuracies in relative isotopic-mass determination of 1 part in 100,000,000.

Experimental Mass Spectroscopy.—An experiment with a mass spectrometer involves: (1) the production with an ion source of an ion beam characteristic of the sample under investigation; (2) separating the beam into various mass components with a mass analyzer; and (3) rendering the resolved beam observable with an ion detector. Any device that combines these parts and functions is classed as a mass spectrometer. A typical combination is shown in fig. 2.

ION SOURCES

The production of an ion means in its simplest case the detachment of one or more electrons from a neutral atom. The production of an ion beam is accomplished by accelerating ions by means of electric fields and directing them through small holes or slits. The beam is thus collimated by the slit and has an energy or velocity that can be computed from the voltage through which the ions were accelerated. There are a number of mechanisms for producing ions.

Gaseous-Discharge Ion Source.—The gaseous-discharge ion source was used almost exclusively until 1920. It was developed by Goldstein in 1886 and was improved by Wien, Thomson, Aston and others. Ions are produced by a gaseous discharge maintained (at low gas pressures) by high voltage between two electrodes. The ions are accelerated by the same field and pass through holes in the electrodes as a beam. Although this source is simple in concept and construction, no complete theoretical explanation has been made despite a great deal of work. By 1940 it had been replaced by other sources that are simpler in theory and is now relegated to occasional special applications.

Solid-Loaded Gas Discharge.—The simple gas-discharge source is limited to the ionization of substances with appreciable vapour pressures at room temperature. This limitation is removed by the solid-loaded gas method introduced in alternate forms by E. Gehrcke and O. Reichenheim in 1906 and by Bainbridge in 1932. The method is based on the introduction of the solid material to be analyzed into small holes drilled in the anode or cathode of a gas-discharge ion source. Operation of the gaseous discharge in the supporting gas evaporates and spatters the solid

material into the discharge chamber as ions and as neutral atoms. Further ionization takes place in the discharge itself. Since the source depends on a gaseous discharge the limitations are quite similar to those of the simple gas-discharge source.

Gaseous Discharge in a Magnetic Field.—In 1937 F. M. Penning developed an ion gauge (i.e., a pressure-measuring device) in which a gaseous discharge takes place in a magnetic field. This discharge is much more stable and operates over a much wider pressure range than the simple gaseous discharge described above. Ions can be drawn from such a discharge either axially or at right angles. The ion beams produced are stable and useful for special problems in mass spectroscopy.

Arc Discharge.—The sources noted thus far require only high voltages to maintain the discharge. If a hot filament is used as the negative electrode to supply a continuous stream of electrons, another type of discharge occurs called an arc discharge. This can be operated at much lower voltages than can the simple gaseous discharges, yielding an ion beam more homogeneous as to energy and, hence, more useful in mass spectroscopy. The major advantage of such a source is that it produces an intense ion beam. Since isotopic separators require intense beams, the arc-discharge source is best suited for this application. Its instability is a major factor in making it undesirable for ordinary isotope-abundance work.

Surface Ionization.—The surface-ionization source was discovered by Gehrcke and Reichenheim in 1907. When an atom or molecule is evaporated from a surface it has a probability of being ionized that is given by

$$\frac{\pi^+}{\pi^0} = \exp\left[\frac{e(w-\phi)}{kT}\right]$$

where π^+/π^0 is the ratio of the charged to neutral constituents, e is the electronic charge, w is the work function of the surface, ϕ is the ionization potential of the constituent evaporated, k is the gas constant and T is the absolute temperature. The theory behind this source is thus understood and the special requirements of the source are deducible from the equation. They are: (1) the ionization potential of the material to be analyzed must be low; (2) the work function of the surface from which evaporation takes place must be high; and (3) substances for which the ionization potential is higher than the work function of the surface should be in refractory compounds to take advantage of the temperature sensitivity.

Two variations of the surface-ionization source are used. In one the material to be analyzed is deposited directly on the surface to be heated (filament), and ionization occurs when the material is re-evaporated in vacuum. In the second the sample is introduced as a gas and is ionized when it meets the hot surface. A typical ion source of the former type is shown in fig. 4. It can be used with any type of mass analyzer since the ion energies are homogeneous.

FIG. 4.—TWO VIEWS AT RIGHT ANGLES OF A SURFACE-IONIZATION SOURCE

For many elements surface ionization is the most sensitive of all sources used in mass spectroscopy. It has been used for all isotopic studies of the transuranium elements (*q.v.*) and for most other studies of highly radioactive substances. Its high sensitivity permits work with such small samples that special precautions to protect people from radiation are not required, far outweighing the shortcomings of relatively poor stability.

Vacuum Spark.—The vacuum-spark ion source was developed by Dempster in 1935. In this source a potential of about 50,000 v. is placed between two electrodes. The resulting electrical breakdown produces a hot spot on the electrodes from which solid material is evaporated and scattered into the space between. The electrons present in this space produce ions by bombardment. Further ionization is produced by the impact of ions against the electrodes themselves. A fraction of the ions is then accelerated from the discharge and focused into a beam. To keep the electrode from melting, the voltages are applied as pulses of a few micro-seconds' duration, repeated at a rate of about 60 per second. The source must be used with a double-focusing analyzer for mass resolution since the ion energies are not homogeneous.

The spark source is erratic since it depends on chance electrical breakdown. It does however have the great advantage of roughly constant sensitivity to all elements. It is thus the standard tool for general chemical analysis of solids.

Electron Bombardment.—The electron-bombardment source was introduced by Dempster in 1921. In the 1960s it was the most universally used ion source. Its modern form was worked out by W. Bleakney and A. O. Nier. When an electron collides with an atom or molecule it may lose a fraction of its energy to that atom or molecule in the form of ionization or excitation or both. The ions, whether they are atomic or molecular, are immediately usable. In the case of an atom, the excitation is lost by radiation to, or collision with, the walls of the ionization chamber or by collisions with other molecules having ionization potentials less than the excitation energy. Only the last of these types of energy loss has any influence on mass spectroscopy since it is the only one that results in charged particles. In the case of a molecule, the excitation is often lost by dissociation of the molecule into ionized fragments. Thus, the important characteristic of an electron-bombardment source is ionization with or without fragmentation.

In one variation of the electron-bombardment source the sample is introduced as a gas from an external system; in the other the sample is evaporated from a crucible placed in juxtaposition to the ion source itself. In either case, the sample enters the ionization chamber as a gas and the source itself is unchanged. The source shown in fig. 5 is typical; electrons are produced at the filament by thermionic emission (*see* THERMIONICS). The electrons are accelerated and projected across the ionization chamber by a constant voltage between the filament and the chamber. Since the amount of ionization produced is a function of the elec-

FIG. 5.—TWO VIEWS AT RIGHT ANGLES OF AN ELECTRON-BOMBARDMENT ION SOURCE

tron current and electron energy, it is necessary to regulate both of these quantities. The ions produced by the electron beam are drawn out of the chamber and focused electrically into a beam by the collimating slits. Since ionization in this source occurs in an approximately field-free region, the beam is homogeneous as to energy and the source will work with any type of mass analyzer.

Photo-ionization.—In photo-ionization photons (rather than electrons) produce the ions. Thus if the electron beam of fig. 5 is replaced by a photon beam, the device becomes a photo-ionization ion source. Photon energies required are in the range of 10–20 electron volts; *i.e.*, photons of 500–1,000 Å. These wave

lengths are in the very far ultraviolet range and require windowless light sources. Light sources most used are the many-lined spectra of hydrogen and the continua from helium or argon (*see* LIGHT).

Electron Affinity.—The electron-affinity ion source is based on the fact that an atom or molecule can be evaporated from a surface as a negative ion with a probability given approximately by

$$\frac{n^-}{n^0} = \exp\left[\frac{e(A-w)}{kT}\right]$$

where the symbols have the same significance as in the equation under surface ionization, and A is the electron affinity (*i.e.*, the energy with which an extra electron can be bound to a molecule of the evaporating species. This source is quite similar to the surface-ionization source except that it depends on electron affinity rather than ionization potential, and it produces negative rather than positive ions.

Field Emission.—The field-emission ion source first applied by M. G. Inghram and R. Gomer in 1954 is based on the fact that when very intense electrostatic fields are placed at a surface the absorbed gases on that surface are pulled off as positive ions. Fields of the order of 10^8 v. per centimetre are necessary to draw off such ions. The source is useful mainly in the study of surface chemistry. Since the ions are drawn from an equipotential surface, they are homogeneous as to energy and the source may be used with any of the various mass analyzers.

MASS ANALYZERS

The thousands of mass analyzers that have been constructed can be assigned to a few basic classes depending on their principle of mass separation.

Parabola Mass Analyzer.—If a well-collimated ion beam is projected through parallel homogeneous electrostatic and magnetic fields, it will be resolved into a series of more or less complete parabolas, each characterized by a particular mass-to-charge ratio. The completeness of the parabolas is a measure of the inhomogeneity in energy of the original ion beam; and the structure within a parabola yields information on the ion-molecule reactions occurring in the beam. The parabola mass analyzer is no longer used for analytical purposes because, since it involves no focusing it is a low-resolving-power, low-sensitivity instrument. The major uses are for studying the characteristics of ion sources and for studying ion-molecule collisions.

First-Order Velocity-Focusing Mass Analyzers.—The first mass analyzer to achieve first-order velocity focusing used successive electric and magnetic fields and was constructed by Aston in 1919 (fig. 3). Though four instruments involving first-order velocity focusing have been constructed, they are no longer in use largely because no direction focusing is involved and the ionic transmission is low. The first-order double-focusing mass analyzer has replaced the velocity-focusing analyzer for most purposes.

Velocity-Selection Mass Analyzers.—The crossed-homogeneous electric- and magnetic-field mass analyzer was developed by Wien (1898). If a beam of ions is projected at right angles into such fields, only ions of velocity

$$v_0 = \frac{cE}{B}$$

will traverse those fields without deflection. In this equation, c is the velocity of light, E is the electrostatic field strength and B is the magnetic field strength. If the source produces a monoenergetic ion beam, the velocity is given by

$$v_0 = \sqrt{\frac{2eV_0}{m}}$$

In this equation e is the charge on the electron, V_0 is the potential through which the ion was accelerated and m is the mass of the ion. On eliminating v_0 between these two equations

$$m = \frac{2eV_0B^2}{c^2E^2}$$

it is seen that, in combination with a source that produces an ion beam homogeneous as to energy, the crossed-field arrangement may be used as a mass spectrograph. In addition to mass sensitivity, the arrangement does have the property of direction focusing. Theoretically, an ion beam diverging from a slit within the crossed field will come to focus at distances that are any integral multiple of πa_m from the entrance slit. The quantity a_m is the radius of curvature of the ion path in the magnetic field alone. This analyzer has been little used by itself because of the bulkiness of the equipment necessary to give the desired resolving power. Its main use is in conjunction with other types of analyzers where the property of velocity measurement is of fundamental importance.

Perfect Double-Focusing Mass Analyzers.—The perfect double-focusing trochoidal mass analyzer was introduced by Bleakney and J. A. Hipple (1938). The fields in this analyzer are again crossed-homogeneous parallel electrostatic and magnetic fields, but the trajectories are not straight lines as in the last case but trochoids as shown in fig. 6. This is one of the few analyzers in which perfect double focus occurs; *i.e.*, the focused image is a perfect image of the source slit rather than an approximation. The image occurs for every multiple of $2\pi a_m$ along the x axis where a_m is the radius of curvature of the ion trajectory in the magnetic field alone. The mass scale is exactly linear.

FIG. 6.—TROCHOIDAL TRAJECTORIES OF IONS IN THE PERFECT DOUBLE-FOCUSING CROSSED-FIELD MASS ANALYZER. THE ELECTROSTATIC FIELD IS PLACED IN THE PLANE OF THE PAPER AND IN A VERTICAL DIRECTION. THE MAGNETIC FIELD IS PLACED NORMAL TO PLANE OF THE PAPER

First-Order Direction-Focusing Mass Analyzers.—The first-order direction-focusing mass analyzer was introduced in 1918 by Dempster. The extension of this principle to sector-shaped magnetic analyzers was made by Bainbridge and Nier in 1938. From 1940 until the late 1950s this was the only type of mass-spectrometric equipment available commercially. This type of analyzer can be used only with those ion sources that produce beams homogeneous in energy.

In this analyzer an ion beam homogeneous as to energy is projected at right angles into a homogeneous magnetic field (fig. 7). After deflection, it again comes to focus. The relation between the lengths l'_m , l''_m , ϕ_m and a_m is given by the equation

$$(l'_m - a_m \cot \phi_m)(l''_m - a_m \cot \phi_m) = a_m^2 \csc^2 \phi_m$$

a_m is given by the equation

$$a_m = \frac{m_0 v_0 c}{e B}$$

FIG. 7.—FOCUSING ACTION OF A VECTOR TYPE OF DIRECTION-FOCUSING MASS ANALYZER

It is clear from these equations that from the theoretical standpoint all such instruments are the same regardless of the angle of deflection. The problem of the deflection angle is dictated by such auxiliary considerations as construction requirements. There are, of course, more complicated equations governing the focal conditions in the case of ion beams that do not enter or leave the magnetic field at right angles, but these are different only in detail.

First-Order Double-Focusing Mass Analyzers.—The successive-field first-order double-focusing mass analyzer has been

FIG. 8.—FIELD ARRANGEMENT USED WITH FIRST-ORDER DOUBLE-FOCUSING MASS ANALYZERS. THE DEFLECTION ANGLES ARE ARBITRARY, ANY ANGLES BEING USABLE. HOWEVER, CERTAIN RELATIONSHIPS AMONG l'_0 , l'_m , l''_m , a_m , AND ϕ_m RESULT IN DOUBLE FOCUSING

used extensively for precise mass determinations. After 1945 it was applied to the chemical analysis of solids. Since the device is double focusing (*i.e.*, takes into account spreads in both velocity and direction in the initial ion beam) it will work with any ion source. A typical field arrangement is shown in fig. 8. In this device ions are projected first into a radial electrostatic field that has an energy but no mass sensitivity, and then into a homogeneous magnetic field that has both mass and energy sensitivity. With proper arrangement of the fields, the magnetic field can be made to just cancel the energy sensitivity of the electrostatic field and give an image that is independent of initial ion velocity. At the same time mass resolution does not cancel so that the combination is mass sensitive. Again, any angle of electrostatic and magnetic deflection can be used and the instruments are not different in concept.

Higher-Order-Focusing Mass Analyzers.—By shaping the magnetic field pole faces in first-order-focusing mass analyzers, it is possible to produce higher-order focusing (*i.e.*, more perfect images). Similarly, by using particular combinations of electric and magnetic fields in double-focusing mass analyzers it is possible to produce higher-order focusing in both direction and velocity. The experimental realization of such higher-order focusing is not easy since it is difficult to take accurately into account fringe fields. The most important use of higher-order-focusing mass analyzers is in the determination of the precise masses of isotopes.

Time-of-Flight (RF) Mass Analyzers.—As outlined earlier, a number of different types of mass analyzers have been constructed that depend on time-dependent electrostatic fields for mass sensitivity. By the mid-1960s the pulsed beam, the RF accelerator and the quadrupole analyzers were extensively used for the analysis of the chemical composition of gases.

Composite Mass Analyzers.—There are a number of combinations of the analyzers outlined above which are useful for special purposes. For example, two successive first-order direction-focusing mass analyzers have been used to achieve the advantages of a double achromat in optics. An energy selector followed by a direction-focusing mass analyzer has been used as a tool in molecular energy-level studies.

ION DETECTORS

Photographic-Plate Ion Detectors.—The application of photographic plates to the detection of ion beams was due originally to J. Koenigsberger and J. Kutschewski. Unfortunately the action of fast-moving ions in forming a developable image is poorly

understood. No single law has been found to describe the action satisfactorily. Among the factors involved are:

1. Breaking of chemical bonds of the silver halide molecule by the energetic motion of an atom passing near or through that molecule.
2. Production of light by the atoms excited in the process of stopping the moving atom.
3. Production of secondary electrons.
4. Penetration of the ion through the emulsion.
5. Chemical effects of ionic molecules after stopping as evidenced by excessive sensitivity to some molecules.
6. Gross deposit of ion-beam elements in the emulsion, affecting the rate of diffusion of developing solutions into that emulsion.
7. Charge on the ion.

The relative importance of these effects is a function of the particular emulsion used. For emulsions containing very little gelatin, factor 1 is probably the most important; for emulsions containing a large amount of gelatin and having high light sensitivity, factor 2 is predominant. Thus the sensitivity of a photographic plate is a function of many variables, such as ionic mass, ionic energy, exposure and chemistry. Therefore, photographic plates should be used only when absolutely necessary or when qualitative information is sufficient.

Simple Electrical Ion Detector.—The first use of direct electrical detection of resolved ion beams was due to Dempster (1918). To accomplish this the resolved ions are made to pass through a defining slit and impinge on a collector plate; they are neutralized by electrons flowing to the plate. The flow of this current can be detected with a sensitive amplifier and recorded. The measurement of the relative intensities of the two ion beams is thus simply a matter of reading a meter when first one and then the other ion beam is striking the final collector.

Dual Electrical Ion Detector.—The limitations in the accuracy of a mass spectrometer equipped with a simple electrical ion detector are usually a function of ion-current stability. One method of minimizing the effect of these fluctuations is to collect both beams at once and balance one against the other electrically; *i.e.*, null detection. The use of dual collectors was first reported by H. A. Straus (1941). The arrangement shown in fig. 9 was developed by Nier, Inghram and E. P. Ney in 1947. In this collector one ion beam strikes the defining slit plate and the other passes through to the final collector. The null balance is accomplished with the electronic arrangement shown at the right in this figure.

Suppressive Electrical Ion Detectors.—The suppressive electrical ion detector detects only those ions with full or a known fraction of full energy; *i.e.*, those that have not lost part of their energy by gas collisions or by ion breakup in transit (metastable ions). These collectors are therefore used mainly in applications in which the spectrometer operates at relatively high pressures (leak detection) or where metastable ions are of importance (hydrocarbon analysis). There are three important methods of accomplishing this suppression: (1) by passing the ion beam over a potential barrier; (2) by placing the final collector at such a potential that the beam is decelerated after passing through the image slit and arrives at the final collector with (effectively) zero energy; or (3) by adding an electrostatic analyzer after the image slit to

select those resolved ions of the proper energy.

Electron-Multiplier Ion Detection.—When extreme sensitivity or rapid or panoramic (oscilloscope) recording is of prime importance, the electron-multiplier ion detector is advantageous. The system is avoided whenever possible since it is nonlinear with such factors as ionic mass, ionic energy and stray magnetic field. In addition, with a sensitive spectrometer and most ion sources background peaks are observed at many masses so that the added sensitivity is often useless. The use of electron multipliers can be illustrated from fig. 9. If the final collector plate is removed and the first stage of a standard electron multiplier is put in its place, the secondary electrons produced when the ion beam strikes that plate will be multiplied and detected as a much larger current, thus increasing the sensitivity of the instrument. Such multipliers were first used in mass spectroscopy by A. Cohn in 1941. In his application they were used to count the individual ions striking the final collector. The scintillation ion-beam detector has been used in two forms. In the first the ion beam impinges directly on a scintillator such as potassium iodide and the light pulse produced is amplified with a standard commercial photomultiplier. In the second the beam strikes a plate that converts the beam into electrons; these are accelerated onto a standard scintillator and the light pulse is amplified by photomultiplier for recording. By the 1960s the latter method was used most since in this form the scintillator is not contaminated and spattered away by the ion beam; hence the detector has a much longer useful life.

AUXILIARY EQUIPMENT

Auxiliary components of a mass spectrometer include sample-introduction systems, pumping systems and electronic units.

In the design of sample-introduction systems, special precautions should ensure that the gas in the ionization region is identical or bears some known relationship to the sample being analyzed. Thus, if a gaseous sample is introduced through a leak in which viscous flow predominates, the sample in the source will differ from that being analyzed by the square root of the ratio of the masses. If, on the other hand, molecular flow is used throughout, there will be no difference. Again, if a sample is evaporated from a hot crucible placed in juxtaposition to an electron-bombardment ion source a correction of the square root of the masses is needed if the evaporation is from a solid surface, but not if it is from a liquid surface. Note that in the latter case, as is also true in molecular-flow gas leaks, the composition of the sample itself changes with time. It is apparent that each problem should be considered separately.

The electronic units usually require more space than the three basic components themselves; *i.e.*, ion source, analyzer and detector. The requirements vary so much among the different devices that no general rules can be set up for specifying them for electronic units. They can, however, always be specified starting from the requirements on the three basic units themselves.

APPLICATIONS OF MASS SPECTROSCOPY

The following will summarize only a fraction of the wealth of information that has been obtained through the application of mass spectroscopy. The instruments are used in such fields as physics, chemistry, geology, meteorology, biology and medicine. They are used to analyze microscopic crystals and to control automatically huge gas streams in industrial plants.

Isotopic Existence.—The first mass-spectrometric evidence of isotopes was found in the two parabolas observed by Thomson for neon in 1913. The existence of these isotopes was verified in 1920 by Aston with a velocity-selection mass analyzer equipped with a gas-discharge ion source and a photographic-plate ion detector. From that time the analysis of the isotopic composition of the elements proceeded rapidly. Most were examined by Aston using either gaseous-discharge or surface-ionization sources. In this way he identified 212 isotopes in 74 elements. Other observers analyzed the remaining stable elements and also discovered many rare isotopes in the elements Aston had examined to make up a total of 283 naturally occurring isotopes in the first 83 elements in the periodic table. By the early 1960s, 19 of these 283 isotopes

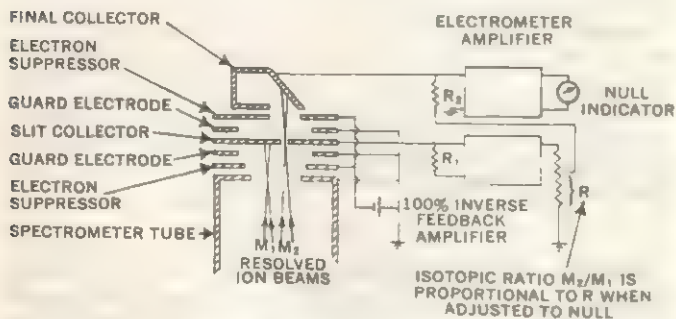

FIG. 9.—ONE ARRANGEMENT OF ION-RECEIVING PLATES FOR DUAL COLLECTION AND NULL MEASUREMENT OF ISOTOPIC COMPOSITION

were known to be radioactive with half lives exceeding 100,000,000 years. All elements with atomic numbers greater than 83 are radioactive; thus the term "naturally occurring" requires interpretation. Only three isotopes above element 83 have half lives comparable with or greater than the age of the solar system: Th^{232} , U^{235} and U^{238} .

The discovery that the chemical elements consist of isotopes with integral values for their masses led to the revival of William Prout's theory of 1815, according to which the atoms of all the elements are different aggregations of hydrogen atoms. This theory had been abandoned toward the middle of the 19th century when precise measurements of the atomic weights of samples of many elements produced results that are definitely not integers. When the nonintegral values were found to result from the presence of isotopes, it was again possible to think of atomic nuclei as built up of different numbers of fundamental units (*see* NUCLEUS). These units were considered in 1920 to be protons and electrons, but after the discovery of the neutron by Sir James Chadwick and the development of the theory of exchange forces by W. K. Heisenberg in 1932, the building blocks (nucleons) were supposed to be protons and neutrons, the number of protons being equal to the nuclear charge and the total number of nucleons being equal to the isotopic mass. More precise comparisons soon showed, however, that the masses of isotopes depart slightly from exactly integral ratios, as will be discussed below.

Radioactive Isotopes.—Isotopes were found in the naturally radioactive elements as early as 1906. The chemical identity of several pairs and groups of radioactive products was well established by 1913, when the term isotope was first introduced. Between the thallium isotope of mass number 205 and the uranium isotope of mass number 238, 40 different kinds of radioactive atoms were known and classified into 10 groups with different chemical properties. The different groups constitute different elements with two to eight isotopes each.

The confirmation in 1934 by Irène Joliot-Curie and Frédéric Joliot of earlier claims of induced radioactivity, that stable isotopes of boron and aluminum could be transformed into radioactive forms by the impact of alpha-rays, led to an unexpected extension of knowledge of isotopes. Protons, deuterons and especially neutrons also were found to produce radioactive isotopes. By the 1960s more than 1,000 so-called active isotopes had been produced (*see* RADIOACTIVITY.) Their masses not only occupy the gaps between the stable isotopes but extend to lighter and heavier masses.

In many cases a particular isotope, identified by its half life, can be formed in several ways from neighbouring elements and it is possible to deduce its mass from its relation to the stable isotopes. However, the occurrence of isomeric forms often introduces uncertainty.

The masses of many active isotopes have been observed directly by the methods of mass spectroscopy. For this purpose the radioactive sample mixed with stable isotopes is used in the ion source of a mass spectrograph. The isotopes separated by the mass analyzer are allowed to fall on a photographic plate or other collecting plate and the positions of the radioactive isotopes are identified, either by means of a counter tube or by making a transfer in which the radiations from the radioactive isotopes produce images on a second photographic plate placed in contact with the original deposits.

Relative Abundance of Stable Isotopes.—The relative abundance of the isotopes of an element may be found either by comparing the relative ion currents in the resolved ion beams characteristic of each isotope or by photometric measurements of their images on a photographic plate. The latter method was used by Aston with the many elements he analyzed. Current measurements give more accurate values; this method has been used to measure the abundances of all of the isotopes.

In the case of hydrogen, carbon, oxygen, sulfur, rubidium and lead the mass spectrometer has detected slight differences in the relative abundances of the isotopes as they occur in nature. The carbon isotope at mass 13 is more abundant in organic samples (1:88.3) than in limestones (1:92.3). Lead samples from differ-

ent sources vary markedly because of the admixture of some lead from radioactive decay. Water from various sources varies in density because of variations in the relative abundance of the oxygen isotopes (M. Dole, 1936). The strontium found in certain micas, formed by the radioactive decay of rubidium, consists almost entirely of an isotope at mass 87 (Mattauch, 1937).

Absorption of neutrons produces samples with very abnormal isotopic abundances, especially in the case of elements with large neutron-absorption cross sections; for example, cadmium, samarium, gadolinium or mercury.

Exact Masses of the Isotopes.—All quantities in physics are relative; exact mass actually means the ratio of an unknown mass to an arbitrary unit of mass. For many years there was a great deal of confusion about the atomic mass scale because it was defined in different ways. Physicists defined the atomic mass unit (amu) in terms of the lightest isotope of oxygen, assigned exactly 16 amu. Chemists defined the mass unit in terms of ordinarily occurring oxygen (a mixture of three isotopes: mass numbers 16, 17 and 18). The difference in the two scales was 0.0275%. As a result such quantities as Avogadro's constant (*q.v.*) and the faraday were different on the two scales, leading to much ambiguity. The two scales were replaced by international agreement in 1961 with a single scale based on the lightest isotope of carbon, assigned a mass of exactly 12 units (12 u). The u designation was selected to distinguish it from the old atomic mass unit (amu). The new unit shifts chemical atomic weights by about 0.004%; for all practical chemical purposes the old scale can be used without correction (*see* ATOMIC WEIGHT). However, appropriate corrections must be made in using the physicists' older atomic mass tables. The correction reduces masses based on the oxygen isotope by 0.0318%.

The determination of precise masses of isotopes with the mass spectroscopy is fundamental for understanding the structure of atomic nuclei. Such measurements led to the discovery of basic relations governing energy release in nuclear transformations, a most important chapter in the subject of mass spectroscopy.

The discovery by Aston (1920) that the mass of hydrogen was 1.008 when compared with oxygen defined as mass 16.0000 was of great importance; for the empirically measured masses of all the nuclei above hydrogen are slightly less than would be expected if these nuclei were simply multiples of the hydrogen mass. One feature of the relativity theory formalized by Albert Einstein in 1905, that the relationship between mass change and energy change is $\Delta E = \Delta mc^2$, entered in a very general way.

The mass of any physical thing could be regarded inherently as an aspect of a hypothetical energy content; thus any change of the energy involved a corresponding change of mass. From the mass-spectroscopic results of 1920 it could be assumed that isotopes are built of hydrogen and that the loss of approximately 0.008 atomic mass units for each hydrogen atom was accounted for by the energy lost when the elements were formed. Conversely this is the energy that would have to be put into the nucleus to remove a proton (hydrogen nucleus) from that heavier nucleus.

Mass measurements made by Aston (1920-27) of the most abundant isotopes of 20 elements were enough to show the general nature of the nuclear binding energies; for example, he found the atomic mass for hydrogen was 1.008, helium 4.004, sulfur 31.982, argon 39.975, mercury 200.61. All these numbers are very nearly integers. Because the difference between the exact mass and the nearest integer was always small Aston introduced the term packing fraction (*P.F.*), which is a measure of the deviation from integral masses. It is defined as

$$P.F. = \frac{M - I}{I}$$

where M is the precise mass and I is the nearest integer to that mass. Although *P.F.* data were commonly given up to the mid-1950s, the term has little physical significance. By the 1960s almost all data on precise masses were given in terms of the average binding energy per nucleon.

The discovery by J. D. Cockcroft and E. T. S. Walton in 1932 of the artificial disintegration of lithium by rapidly moving protons

to form isotopes of helium offered hope of verifying Einstein's mass-energy equation. It was immediately apparent, however, that the then available figures for mass were of such poor precision that the accuracy in the quantitative relation would be no better than 50%. It was evidently necessary to improve mass measurement to yield results accurate to five or six significant figures. This led Dempster, Bainbridge and Mattauch to develop double-focusing mass analyzers. With the first of these Dempster (using the vacuum-spark ion source) investigated the four remaining elements that had been too difficult to study with the older analyzers. In these and 13 other elements he found 33 isotopes that had been missed on the earlier equipment, including the rare isotope of uranium U^{238} . The spark source formed a great number of multiple-charged ions and made possible 60 accurate mass determinations among the heavier elements. Bainbridge and E. B. Jordan with their double-focusing device measured the mass of 14 of the light elements with great accuracy. Mattauch with his equipment made 12 comparisons and deduced seven precise masses. Other devices were completed by T. Okuda (1939) and Jordan (1940), the latter having a resolving power of 30,000. Thus in eight years the resolving power of mass spectrometers had improved from 130 to 30,000; by the mid-1960s Nier, Mattauch, H. E. Duckworth and others had further improved the instruments. Resolutions achieved were 1 part in 750,000 and accuracies in isotopic-mass determination were 1 part in 100,000,000. A graph showing average binding energy per nucleon is shown in fig. 10. Note that the vertical scale covers a variation in binding energy of less than 5%. The information exhibited by fig. 10

FIG. 10.—THE AVERAGE BINDING ENERGY OF ISOTOPES AS A FUNCTION OF ISOTOPE MASS NUMBER. THE DASHED CURVE CONNECTS ISOTOPES OF ODD MASS. THE PARABOLIC LOOPS REPRESENT ISOTOPES OF EVEN MASS FOR EACH ELEMENT. THE LIGHT-MASS ELEMENTS ARE FAR OFF SCALE IN THE DOWNWARD DIRECTION

is remarkable; it represents detailed experimental verification of the mass-energy relation of relativity theory and constitutes a major scientific achievement. What had been a grandiose theoretical formulation of 19th-century physics is shown to apply in one of its fundamental features to the partially explored field of nuclear phenomena.

Ionization Phenomena and Chemical Physics.—Mass spectroscopy grew out of and includes the study of ionization and its resulting reactions. Wien showed in 1900 that ions formed in a gas discharge are characteristic of that gas. Thomson from 1910 to 1913 found with his parabola analyzer that molecular gases may be ionized with or without dissociation, that ions with multiple charges or single negative charges occur and that a variety of reactions take place as an ion moves through a gas.

An important step in the study of ionization phenomena was Dempster's introduction (1916) of electron beams of known energy as ionizing agents. In 1922–30 H. D. Smyth and others gradually reduced the energy of the electrons and improved techniques to the point where thresholds for ionization could be determined. This appearance potential is related to the ionization potentials of elements or molecules and its measurement has proved

important in the quantum theory of atomic and molecular structure (see QUANTUM MECHANICS). In 1930 J. T. Tate and Bleakney determined the kinetic energy with which excited ions dissociate and gave strong impetus to the study of quantum-mechanical energy levels in molecules. Another important step was the introduction (1957) of photon beams of known energy as ionizing agents.

These techniques have now been applied to a wide variety of problems in chemical and molecular physics. These include the determination of bond strengths in molecules; the structure of molecules; the composition of the gases in equilibrium with condensed phases at high temperatures; the kinetics of unimolecular dissociation; the kinetics of evaporation and condensation; cross sections for many kinds of molecular reactions.

Hydrocarbon Analysis.—The study of Smyth, Tate and Bleakney concerning ionization phenomena in gases led by 1940 to the use of the mass spectrometer on an industrial scale for the analysis of hydrocarbons and other gaseous mixtures. In such applications the mass spectrum recorded by a hydrocarbon mixture can be represented as the sum of the intensities of the pure components. Thus by measuring two peaks the relative concentration of a two-component system may be determined. By measuring ten peaks a ten-component system may be analyzed, and so on. Such analyses require the solution of simultaneous equations since most peaks are an admixture of several components. In conjunction with these devices it is therefore important to have a special calculator for solving simultaneous equations. Such calculators became commercially available in 1945. Using this mass-spectrometric method, the analysis of a ten-component hydrocarbon gas mixture takes, on the average, about half an hour; a similar analysis using the older distillation methods would require many hours of work. In addition these instruments have been used directly on gas streams for continuous analysis of industrial plant operation. Instruments used for continuous monitoring are more rugged and correspondingly somewhat less accurate than their laboratory counterparts. In some cases the instruments are connected directly to the plant controls to attain automatic plant operation (see AUTOMATION).

Leak Detection.—Mass spectrometers can be used to detect extremely small amounts of gas mixed with large quantities of other gases. Nier and A. Hustrulid in 1943 constructed a simple direction-focusing instrument for detecting leaks in systems that must be airtight. The system is evacuated and the leak detector is connected to sample the gas remaining. If there is a leak that gas will be air. If a small jet of helium is then allowed to flow over any suspected point in the system the mass spectrometer gives an immediate signal if the helium leaks in. Since the helium content of air is 1 part in 500,000, such a detector can locate 1 leak in the presence of 500,000 other equal leaks. In the mid-1960s there was no other leak detector known with higher sensitivity. Leak-detecting mass spectrometers became available commercially in 1945.

Age of the Earth and Nucleogenesis.—The discovery by Aston that the isotopic composition of lead (Pb) from various sources differed markedly and that the variation arose from the accumulation of radioactive decay products from uranium and thorium, was an impetus to geochronology (*q.v.*), the dating of geological materials. Since radioactive decay products accumulate with time in a predictable way the excess isotopic abundance is a measure of time elapsed since a geologic sample was last altered.

Following Aston's findings and later work by Nier on the technique of age determination, a number of other naturally occurring radioactive isotopes have been found useful for age determination. These include $K^{40} \rightarrow Ar^{40}$, $Rb^{87} \rightarrow Sr^{87}$ and $Re^{187} \rightarrow Os^{187}$ decays. Their application to geologic samples has been a major tool in tracing the history of the surface of the earth. In 1955 methods were first applied to meteorites. The isotopic composition of lead and argon from meteorites indicates the age of meteorites and of the earth to be about 4,500,000,000 years.

How long it took from the time of the formation (nucleogenesis) of the elements that make up our solar system, and the time when the system took on the basic structure it had 4,500,000,000

years ago is of basic importance in cosmogony. This time can be measured, or at least something related to it can be measured. If a decay product can be found from a radioactive substance that has a half life comparable to the time between nucleogenesis and the formation of the earth. J. H. Reynolds detected an effect arising from such an activity in the study of xenon from meteorites. The material responsible for the decay was an isotope of iodine, I^{129} . In the mid-1960s the interpretation of the data was still uncertain. However there was general agreement that nucleogenesis took about 500,000,000 years, beginning about 5,000,000,000 years ago. See also COSMOGONY; RADIOCARBON DATING; and references under "Mass Spectroscopy" in the Index.

MASSYS (MATSYS, METSYS, MESSYS), QUENTIN (QUINTEN) (1466?–1530), Flemish artist and the first important painter of the Antwerp school, was born at Louvain, where he learned the trade of blacksmith. During the greater part of the 15th century the centres in which the painters of the Low Countries most congregated were Bruges, Ghent and Brussels. Toward the close of the same period Louvain took a prominent part in giving employment to workmen of every craft. It was not until the opening of the 16th century that Antwerp usurped the lead which it afterward maintained against Bruges and Ghent, Brussels, Mechlin and Louvain. Quentin Massys was one of the first men of any note who gave repute to the guild of Antwerp. A legend relates how the smith of Louvain was induced by affection for the daughter of an artist to change his trade and acquire proficiency in painting. Van Mander does not give us the name of Massys' master. Massys was ten years old when Dierik Bouts died at Louvain, and his style was probably formed by the Bouts tradition, which survived in the workshop of Dierik's son Albert. In 1491 Massys went to Antwerp, and was there admitted into the guild of St. Luke. He was one of the first men of any note in the guild of that city, which was then rapidly becoming the most important commercial centre in the Netherlands.

Early works by Massys are two pictures of the Virgin and Child in the Brussels gallery. His most celebrated pictures are two large documented altarpieces, the triptych of the "Marys of Scripture Round the Virgin and Child," which was ordered for St. Peter's church in Louvain (1507–09), now in the Brussels gallery, and the triptych of the "Pieta" (c. 1508–11), which he executed for the joiners' company in the cathedral of Antwerp, now in the Antwerp gallery. These pictures display great earnestness in expression, strong religious feeling, great minuteness of finish and a general absence of light or shade. As in early Flemish pictures, so in those of Massys, excessive care is lavished on jewelry, edgings and ornament. There is a tendency to accentuate individual expression. This is illustrated in such pictures as "The Old Man and the Courtesan" in the Pourtales collection, Paris, and "The Banker and His Wife" in the Louvre, where an attempt is made to display cupidity and avarice. The "Ecce Homo" and "Mater Dolorosa," at Antwerp, display serenity and dignity. Very attractive are his pictures with figures on a smaller scale, such as the polyptych in Munich, the scattered parts of which have been fitted together, and "The Virgin and Child" in the Aynard collection in Paris. His landscape backgrounds are often in the style of Patinir, who came to Antwerp in 1515 and is said to have painted backgrounds for some of Massys' pictures. "The Crucifixion," in the Liechtenstein collection, is believed to be the joint work of the two masters.

In 1517 Massys painted many great portraits, including those of Erasmus and Peter Gillis, to be sent to Sir Thomas More. The original of the Erasmus may be the portrait in the Corsini palace in Rome; the Gillis, in Lord Radnor's collection, drew from Sir Thomas More a eulogy in Latin verse. Other portraits are in the museums of Chicago and Oldenburg (Ger.) and in the collection

ALINARI ART REFERENCE BUREAU

"THE BANKER AND HIS WIFE," SIGNED AND DATED "QUENTIN MATSYS SCHILDER 1514," OIL ON WOOD PANEL, LOUVRE MUSEUM

of the prince of Liechtenstein. The man with a pair of eyeglasses in the Städel gallery at Frankfurt, Ger., is full of vitality; he seems to be speaking. The Musée André, Paris, has an expressive profile of a man, signed and dated 1513. The artist obviously aimed at depicting the desires and emotions of the men of his day.

When compared with portraits by Dürer or Holbein, Massys' art appears subjective and personal. He came into contact with both German masters, for both in turn visited him in his house at Antwerp. Dürer's first call was made in Aug. 1520. The two men must have had much in common, for they were both humanists. The lost original of Massys' "St. Jerome in His Study," of which there is a copy in Vienna, owed something to Dürer's "St. Jerome," now at Lisbon. Holbein, as a young man, passed through Antwerp in 1526 on his way to England, and he carried an introduction from Erasmus to Gillis, who was to send him to Massys' house. The question as to how much Massys was indebted to the Italian art of his time is difficult to determine. There is a picture by him from the Raczkinski collection, in the museum at Poznan (Pol.), representing the Virgin and Child playing with the lamb. These figures are obviously copied from Leonardo's famous "St. Anne, the Virgin and Child," now in the Louvre, except that the St. Anne is left out, and the group is placed on a landscape background in the style of Patinir.

Quentin Massys died at Antwerp in 1530. He had two sons who were artists.

JAN MASSYS (1509–1575) was at first a weak imitator of his father. He became master in the guild of Antwerp in 1531, was banished for his heretical opinions in 1543 and stayed away until 1558. During these years he is supposed to have visited Italy or France. An early picture by him is the "Virgin Kissing the Child" in the church of St. James at Antwerp, which imitates the "Madonna Enthroned" by his father, now at Berlin. A half-length "Judith," now in the museum at Boston, is of a later date and seems to recall Italian or French influences. To the same class belongs the "Lot and His Daughters," at Vienna, dated 1563.

CORNELYS MASSYS (1513–1579) became a master painter in 1531. There is a signed picture of him at Amsterdam, dated 1538, representing the prodigal son; also a genre picture, signed and dated 1543, at Berlin. He painted landscapes in the style of his father, and he was also an engraver.

MASTABA, in Egyptian architecture, a rectangular cut stone tomb, with sloping sides and a flat roof, usually containing three chambers. In the first chamber the walls were sometimes richly decorated with paintings, and there was a low bench of stone on which incense was burned. The second (*serdab*), containing the image of the deceased, was either closed, with holes pierced in the wall separating it from the first chamber, or entered through a narrow passage, through which the fumes of the incense passed. A vertical wellhole descended to the third, in which the mummy was laid. See EGYPTIAN ARCHITECTURE.

MASTER, a man having a position of authority. The word is derived from the Latin *magister*, the original meaning being perhaps best seen in compounds such as master mason and master cook. But, even in classical times, *magister* had acquired the special connotation of schoolmaster; its principal English usage is still perhaps in this sense. (In this sense it is often adjectivally qualified, and many Englishmen are unaware of the subtle distinctions among master, schoolmaster, high master, head master and headmaster.) The word has other uses, as for an employer; for the captain of a British merchant navy ship; for some heads of university colleges and of other institutions; for the head of the household; and in such compounds as master-craftsman.

In the universities the main usage is related to that in the schools: the master of arts (*magister artium* or M.A.; in the U.S., often *artium magister* or A.M.) is in theory the holder of a licence to teach. The term "master" was originally equivalent to that of doctor; in the faculty of arts the approved scholar was styled master, while in faculties of divinity, medicine and law he was termed doctor. Perhaps because of the need to become a master of arts before proceeding to other studies, the doctorate came to be esteemed as a higher title. In modern usage in most universities, except in Scotland, the gradation in the faculty of arts is B.A., M.A., Ph.D., D.Litt. The automatic conferring of an M.A. degree upon the holder of B.A. seven years, or nearly seven years, after matriculation is practised at Oxford and Cambridge, but elsewhere in England, and in the U.S., the M.A. must be achieved through examination or by the completion of a piece of research. See also DEGREE, ACADEMIC.

MASTER AND SERVANT. This is the traditional name for the legal relationship between the parties to a contract by which one agrees to work for another who, for wages or other consideration, acquires the right to control the work in performance as well as in the result. With its connotation of menial duty, the name is an anachronism and gradually is giving way to expressions such as "employer and employee." However, the phrase "master and servant" is too deeply embedded in Anglo-American jurisprudence for early extinction.

The concept is important in defining common-law rights and obligations attending contracts for personal service, and especially in applying the doctrine of *respondet superior* by which the master, though faultless, is liable for damages to third persons caused by the tort of his servant in the scope of employment. Occasionally, for reasons of social policy, vicarious liability has been imposed on the master under the law of crimes. The master-servant concept is also significant because it often determines the ambit of social legislation such as minimum wage laws and unemployment insurance acts.

While the master's right of control has been regarded as the essential distinction between servant and independent contractor, other criteria are relevant and sometimes decisive. These include the duration, continuity and exclusiveness of the relationship; the integration of the worker's duties as part of an enterprise; and, conversely, the extent to which he invests capital (as by furnishing equipment or place of work) and shares in profit and loss.

The relationship is contractual, and therefore requires mutual manifestations of assent. However, the contract need not be evidenced in writing and need not even be express, provided that a contract can be inferred from the parties' conduct. Once a

contract is found, its terms may be supplemented (and sometimes superseded) by implication or operation of law, or by collective bargaining.

If the contract fails to specify length of employment, the English courts have tended to infer some definite duration, based upon custom, agreed pay period or the like. U.S. courts have tended to find in such a contract mere employment at will. There is no conflict between these views, however, for both purport to derive the intent of the parties from context. While U.S. industry has been characterized by employment at will, the employee is often protected by a collective bargaining agreement requiring "just and proper cause" for discharge.

A servant is normally under obligation, express or implied, to perform his duties diligently, with appropriate care and skill, obeying all reasonable orders of his master and avoiding use of his position for a purpose detrimental to the master's interests. In turn, the master must exercise due care, as specified by statute, to protect the servant from physical hazards of the work. During the 19th century, English and U.S. courts developed the defenses of contributory negligence, assumption of risk, and common employment (the last was a rule, since abrogated, denying the master's liability for injury by a fellow servant), so that employers were virtually insulated from tort liability to their employees. This result was consistent with the prevailing policy of encouraging capital investment, but a spreading belief that it was unjust led to adoption of employers' liability and workmen's compensation acts.

See AGENCY; LABOUR LAW; WORKMEN'S COMPENSATION.

(C. H. L.)

MASTER OF THE ROLLS, in England, originally chief of the 12 clerks or masters in chancery and, as such, keeper of the rolls, or records of the chancery, especially the register of original writs, and all patents and grants under the great seal. He was first called master of the rolls in the statute 2 Hen. VIII, c. 18. Before and after this date he is sometimes called vice-chancellor, since with the development of the chancery as a court, he was called upon to sit at first with the justices or with two or more masters; later, in the absence of the chancellor, by himself for judicial business. In fact he became the deputy of the chancellor. Meanwhile he had long ceased to be keeper of the records, but by the Public Record Office act of 1838 their custody was restored to him. He is now also chairman of the State Papers and Historical Manuscripts commissions. Since the Judicature act of 1875 and the Appellate Jurisdiction act of 1876 he is in effect the president of the court of appeal, whose decisions can be questioned only in the house of lords.

(W. T. Ws.)

MASTERS, EDGAR LEE (1860-1950), U.S. poet and novelist, author of *Spoon River Anthology*, the first of the many works representing the "revolt from the village" in American literature. was born at Garnett, Kan., Aug. 23, 1869. He attended Knox college, Galesburg, Ill., for one year, was admitted to the bar in 1891 and developed a good law practice in Chicago. A volume of his verses appeared in 1898, followed by *Maximilian*, a drama in blank verse (1902); *The New Star Chamber and Other Essays* (1904); *Blood of the Prophets* (1905); and a series of plays issued between 1907 (*Althea*) and 1911 (*The Bread of Idleness*).

If Masters had continued to write along these lines, he would not be remembered; but forces were at work on him that would soon induce him to write a work that stands as one of the most significant American books of the early 20th century. In 1909 his friend William Marion Reedy of St. Louis, Mo., editor of *Reedy's Mirror*, introduced him to *Epigrams From the Greek Anthology* (see ANTHOLOGY). Masters was seized by the idea of composing a similar series of free-verse epitaphs in the form of monologues spoken from the grave by former inhabitants of Spoon River, a fictitious village compounded of Petersburg and Lewistown, Ill., as he had known them as a boy. The result was *Spoon River Anthology* (1915).

Though Masters continued to publish almost yearly during the rest of his life, the quality of his work never again rose to the level of the *Spoon River Anthology*. Other volumes of verse are

Songs and Satires (1916); *The Great Valley* (1916); *Toward the Gulf* (1918); *Starved Rock* (1919); *Domesday Book* (1920); *The New Spoon River* (1924); *The Fate of the Jury* (1929); *Godbey* (1931); *Richmond* (1934); *Invisible Landscapes* (1935); *Poems of People* (1936); and *Illinois Poems* (1941).

Among his novels are *Mitch Miller* (1920) and *The Nuptial Flight* (1923). Masters wrote biographies of Lincoln (1931), Whitman (1937) and Mark Twain (1938); his best effort in this form is *Vachel Lindsay, A Poet in America* (1935), a study of his friend and fellow poet. Also notable are his autobiography, *Across Spoon River* (1936), and *The Sangamon* (1942), a volume in the "Rivers of America" series.

Masters died at Philadelphia, Pa., on March 5, 1950.

MASTIC (MASTICH), a resinous exudation obtained from the lentiscus (*Pistacia lentiscus*), an evergreen shrub of the cashew family (*Anacardiaceae*; q.v.). The lentisk or mastic plant, in the same genus as the pistachio tree, is indigenous to the Mediterranean coast region from Syria to Spain but grows also in Portugal, Morocco and the Canary Islands. The production of the substance has been, since the time of Dioscorides, almost exclusively confined to the Greek island of Chios in the Aegean sea. The shrubs are about six feet high.

The resin is contained in the bark and not in the wood, and in order to collect it numerous vertical incisions are made, during June, July and August, in the stem and chief branches. The resin speedily exudes and hardens into oval tears, which are collected every 15 days. The collection is repeated several times between June and September, a fine tree being found to yield about eight or ten pounds of mastic during the season. Mastic occurs in commerce in the form of roundish tears about the size of peas. They are transparent, with a glassy fracture, of a pale yellow or faint greenish tinge, which darkens slowly. It is used in making a pale varnish for coating metals and paintings and as an adhesive and cement in dental work.

Other *Pistacia* trees, growing from India to the Mediterranean, yield a kind of mastic. In Algeria, *Pistacia atlantica* yields a solid resin. Cape mastic is the produce of *Euryops multifidus*, the resin bush, or *harpis bosch* of the Boers—a plant of the family Compositae. Dammar resin is sometimes sold under the name of mastic. The West Indian mastic tree is *Bursera gummifera*, and the Peruvian mastic, or California pepper tree, is *Schinus molle*. The name is also applied to a timber tree, *Sideroxylon masticodendron*, family Sapotaceae, which grows in the West Indies and on the coast of Florida.

MASTIGOPHORA, alternative name for the Flagellata, a group of protozoans characterized by having one or more thread-like processes called flagella. See PROTOZOA.

MASTODON, the common and generic name (synonymous with *Mammus*) of extinct elephantlike proboscideans; the term, sometimes as "mastodont," is applied generally to various other related forms. As a group, mastodons were numerous, widely distributed and extremely diversified during much of the Tertiary period. These mammals were probably haired. They invaded all of the northern continents, and even reached South America, apparently living in herds that rivaled the American bison of the 19th century. Only a few, including *Mastodon*, persisted into the Pleistocene epoch or Ice Age (about 1,000,000 years ago).

The earliest and most primitive mastodon was *Palaeomastodon* from the Lower Oligocene epoch of Egypt (about 40,000,000 years ago). It was the size of a large pig, with massive skull, heavy legs and an elongated proboscis or trunk. As in all mastodons, certain incisor teeth were greatly enlarged to form tusks, usually two above and two below. The cheek teeth or molars, six above and five below on each side, were large and equipped with many cusps on the grinding surfaces. In the course of their evolution,

BY COURTESY OF CHICAGO NATURAL HISTORY MUSEUM

PAINTING OF A MASTODON BY CHARLES R. KNIGHT IN THE CHICAGO NATURAL HISTORY MUSEUM

mastodons increased in size and in elaboration of their tusks. In height they seldom exceeded nine feet. Tusks of some mastodons were as long as ten feet, but a length of seven to eight feet was usual. In some forms the lower tusks were short or absent, in others they were long and spirally twisted or broad and touching, forming a scoop; some tusks curved up and out, others down.

The mastodons represent the main line of development of the proboscideans, with many side branches. One of the early side branches developed in somewhat parallel fashion, culminating in the mammoths (q.v.). From this latter branch, in relatively recent times, our modern elephants (q.v.) originated. Compared to the mammoth, the mastodon had a low forehead, massive limbs and an enormously broad pelvis; compared to modern elephants, it had a shorter and higher brain case, longer limbs and low-crowned molars, with fewer ridges, all in place simultaneously.

The best-known example from North America is *Mastodon americanus*, a large, two-tusked mastodon of the Pleistocene epoch. Numerous skeletal remains have been found in postglacial swamps and peat bogs, over most of the United States and northward to Lake Winnipeg and British Columbia, with other records from Nova Scotia and Alaska. Carbon-14 dating methods indicate that this mastodon survived until 8,000 or 10,000 years ago. It was probably contemporaneous with early man, who may have hunted it and contributed to its extinction, as attested to by pieces of charcoal and broken pottery found associated with mastodon bones.

See PROBOSCIDEA; see also PALEONTOLOGY. (R. H. MA.)

MASTOIDITIS is almost invariably secondary to acute or chronic disease in the middle ear. In some instances inflammation may spread into the mastoid antrum and the mastoid cells following otitis media, but when the infection is very severe the whole middle ear cleft, which includes the mastoid region, is infected simultaneously. The narrow drainage channels from the antrum and cells are obstructed readily and the degree to which the products of inflammation are penned within the mastoid antrum and cells determines the severity of the mastoid symptoms. The chief symptom is pain behind the ear and over the side of the head, and there may be evidence of increasing toxemia characterized by rise of temperature and pulse rate. Tenderness over the mastoid bone may be marked and, as the condition develops, there is increased swelling of the tissues overlying the mastoid bone. The swelling may increase until a fluctuant abscess develops; this indicates that the infection has eroded the bone and destroyed the cortex (outer layer) of the bone. Different forms of abscess are described according to the structures involved; e.g., zygomatic abscess, or Bezold abscess spreading down the neck. In some circumstances the mastoiditis, instead of coming to the surface, may involve structures within the cranium and so give rise to complications. The most important of these are abscess without or within the dura mater covering the brain, infec-

tion and thrombosis of the lateral sinus (the large blood channel flowing into the internal jugular vein) and infection of the labyrinth containing the balance and hearing apparatus. In addition, meningitis is an outstanding danger.

Mastoiditis is treated by the early administration of antibiotics. At one time a frequent and dangerous disease, it is now rare, owing to the effective treatment by modern drugs of the preceding otitis media. In the few cases that do not respond to these remedies, surgical drainage with wide removal of diseased bone is demanded.

Chronic mastoiditis is a part of the disease of chronic otitis media and results from unresolved attacks of acute mastoiditis. Acute exacerbations of chronic mastoiditis may produce any of the symptoms and signs already described. Its treatment is surgical and is undertaken when operation is carried out for the cure of chronic otitis media. The conditions most frequently confused with mastoiditis are furunculosis of the external auditory meatus, erysipelas and inflammation of glands overlying the mastoid bone.

(I. S. H.)

MASUDI, AL- (ABU-AL-HASAN 'ALI AL-MAS'UDI) (d. c. 956), Arab traveler and historian, known as "the Herodotus of the Arabs," was born at Baghdad toward the end of the 9th century. His travels extended to Palestine, Persia, Armenia, the shores of the Caucasus, India, Ceylon, the China seas, Madagascar, Zanzibar and Oman. He was in Antioch in 943 and in Damascus two years later. The last ten years of his life he spent in Syria and Egypt, dying at Al Fustat (Old Cairo) in 956 or 957. Himself a rationalist (Mu'tazilite) he took his information, when necessary, from Persians, Jews, Indians and even the chronicle of a Christian bishop. His historical works included *Kitab akhbar al-Zaman*, in 30 volumes, and a supplement *Kitab al-Awsat*, a chronological sketch of general history. Only one volume of the former has survived but the two parts were epitomized in *Muraj al-Dhanab wa Ma'adin al-Jawahir* (French translation by C. Barbier de Meynard and P. de Courteille, *Maqoudi: les prairies d'or*, 9 vol., 1861-77). In the last year of his life he wrote *Kitab al-Tanbih wa-al-Ishraf* (French translation by B. Carra de Vaux, *Maqoudi, le livre de l'avertissement et de la revision*, 1897) in which he summarized, corrected and completed his former writings. Masudi's historical works are somewhat superficial as he accepted many unauthenticated stories and seldom went to original sources, but they are enlivened by his boundless curiosity and interest in the world and marked by many anecdotes drawn from his travels and his observation of strange places, peoples and animals.

See C. Field, *Tales of the Caliphs* (1909), based on Masudi's history; R. A. Nicholson, *Literary History of the Arabs*, 2nd ed., pp. 352-354 (1930).

MASULIPATNAM (formerly MASULIPATAM; also BANDAR), a seaport and the administrative headquarters of Krishna (Kistna) district, Andhra Pradesh, India, lies between a distributary of the Krishna river and a canal of its delta system, 215 mi. N.N.E. of Madras. Pop. (1961) 101,417. The town was made a municipality in 1866. Robertson square, in the middle of the town, is the main traffic centre. The fort, now in ruins, with the Tomb of the Dead erected in memory of the 30,000 who died in the great storm of 1864, Volandalapalem and Frenchpet (where formerly the Dutch and French resided) are places of interest. There are three colleges, including a Sanskrit college, all affiliated with Andhra university, and an engineering institute.

The port is only a roadstead, vessels having to anchor 5 mi. out. It is connected by a branch line from Vijayavada (Bezvada) with the main Madras-Calcutta railway, and by the Bandar canal with the canal system from the anicut on the Krishna river at Vijayavada. The town is noted for its manufacture of scientific instruments, and the traditional (but declining) industry of weaving chintzes and carpets.

Masulipatnam was the earliest English settlement on the Coromandel coast (q.v.), and important as the *bandar* or port of Golconda. An agency was established there in 1611. In 1686-90 it was held by the Dutch. During the wars of the Carnatic, the English were temporarily expelled from the town, which was held by the French from 1750. In 1759 the town and fort were stormed and taken by a small force led by Francis Forde, a soldier in the

service of the East India company.

(B. S. R.)

MASURIUM: see TECHNITIUM.

MATACO, the largest and most important Indian tribe of the Gran Chaco, living between the Bermejo and Pilcomayo rivers in northeastern Argentina. Latest available data in the 1960s indicated they numbered about 20,000 of the 68,000 total aboriginal population of the Chaco. Formerly known as Mataguayos, they were until relatively recently considered to form an independent linguistic family, Matacoan or Matacan. The relationship to Macá (Enimaga-Cochaboth) is generally accepted, however, and more distant relationship to the Guaycurú seems so probable that all have been suggested as forming a Macro-Guaycurú linguistic phylum (see table in INDIAN, LATIN-AMERICAN). The Mataco practise considerable agriculture, growing principally maize, pumpkins, sweet manioc and beans, but they still rely on fishing, hunting and wild-food gathering, formerly of far greater importance. Classed as foot Indians, they make slight use of boats or horses.

See W. Revill, *Chaco Chapters* (1947).

(J. A. Mn.; X.)

MATADOR: see BULLFIGHTING.

MATAGALPA, a large department in the central highlands of Nicaragua, and its capital city. The population of the department (1950) was 135,401; (1963) 171,465. Matagalpa is important in agriculture, mining and manufacturing, producing especially coffee (about 20% of the national output), corn, tobacco, potatoes and other vegetables, fruits, brown sugar (*panela*), cattle, swine, gold and silver, processed foodstuffs, furniture, leather goods and clay products.

The city of Matagalpa, pop. (1950) 10,323, (1963) 15,030, is located in the north central part of the department in a highland valley at 2,131 ft. above sea level. It is one of the older picturesque cities of the country. Until well into the 20th century it could be reached only by horseback. A highway 20 mi. long connects Matagalpa with the Inter-American highway at Sébaco, giving it direct connections with Managua 103 mi. distant. The city is the leading trading and manufacturing centre of the department.

(C. F. J.)

MATA HARI (1876-1917), Dutch dancer, courtesan and spy, known also by her real name MARGARET GERTRUDE ZELLE, was born on Aug. 7, 1876, at Leeuwarden in the Netherlands. Married to Capt. Campbell MacLeod, an officer of Scottish origin of the Dutch colonial army, she accompanied him to Java and there learned to practise ritual oriental dances. After divorcing her husband she sailed back to Europe—assumed the stage name of Mata Hari and danced with great success in several European capitals. In 1908 she settled in Paris, where she made full use of her beauty as well as her personal charms and had lovers in French political circles. It was then that she began to act as a secret agent in Germany's pay. She went to Berlin a few days before the beginning of World War I but came back to Paris through the Netherlands in 1915. As she was suspected by both British and French intelligence services, traps were set for her and she was eventually caught. Tried in July 1917 by a French court-martial, she was convicted of being a spy (her number in the German intelligence files was H. 21) and sentenced to death. She was shot at Vincennes on Oct. 15, 1917, having gallantly faced the firing squad.

BIBLIOGRAPHY.—E. Gomez Carillo, *Mystère de la vie et de la mort de Mata Hari* (1925); T. Coulson, *Mata Hari, Courtesan and Spy* (1930); C. S. Heymans, *L'Aveu définitif de l'Allemagne sur le rôle de l'espionne Mata Hari* (1936); Sam Waagenaar, *The Murder of Mata Hari* (1964).

(J. C. DE C.)

MATAMOROS, a town and border port in the Mexican state of Tamaulipas, 28 mi. from the mouth of the Río Grande, on its south bank opposite Brownsville, Tex. Pop. (1960) 92,327. It is a commercial centre for the Mexican portion of the lower Río Grande valley. Trade via the Gulf of Mexico is impeded by sand bars at the river's mouth. By international treaty effective Nov. 8, 1945, Mexico and the United States undertook to provide a series of dams and allied works across the river, chief of which are the international Falcón dam, 75 mi. down river from Laredo, Tex.; and, on the Mexican side, Anzalduas dam and canal, whose irrigation district of 540,000 ac. (a thriving cotton area) depends on Matamoros.

The city has rail outlets to Monterrey and Mexico City, and also has highway and air connections. It was the scene of bitter fighting in the U.S.-Mexican War, and was captured by U.S. troops (May 1846). Matamoros is one of Mexico's chief ports of entry for tourists and for the import and export of goods.

(J. A. Cw.)

MATANZAS, a province and its capital city, in west-central Cuba. The province was established in 1879 between Havana province on the west and Santa Clara (now Las Villas) on the east and south. It is the smallest province in population (1953 census, 395,780 [1961 est.] 427,088), and next to smallest in area (3,260 sq.mi.). Its fertile plains have supported a prosperous sugar industry since colonial days. Various industries have been developed at Matanzas and Cárdenas, the port cities, and at Colón on the Central highway. The province's tourist attractions include Yumurí valley, Bellamar caves and Varadero beach.

The city of Matanzas was founded in 1693 on an excellent open bay, which had been known to the Spanish since 1508 and had been used by pirates. By 1860 it was the second city of Cuba, having 30,000 inhabitants, but its growth thereafter was slow as the sugar industry expanded into the eastern part of the island. Pop. (1953) 63,916. In the mid-19th century Matanzas exported more than one-third of Cuban sugar. It has been called the Athens of Cuba because of its active cultural institutions, public library, and famous poets, sculptors and artists. The city has beautiful drives, plazas and monuments, as well as historic buildings, such as Castillo de San Severino and San Carlos, the oldest church, founded in 1730 and raised to the rank of cathedral in 1915. Monserrate shrine, located on La Cumbre hill, overlooks the Yumurí valley back of Matanzas.

Matanzas, about 50 mi. E. of Havana, is one of the chief ports of Cuba, exporting sugar and henequen fibre. The establishment of a free zone in its spacious harbour has resulted in the expansion of industry, chief of which is a large rayon fibre factory. Other plants manufacture ropes, shoes, fertilizers and matches. Matanzas is linked to Havana by two railways, one of which is the electrified Hershey railroad, and by the Central highway.

(D. R. D.)

MATARA, a town and coastal district in Southern province, Ceylon. The town, capital of the district, lies at the mouth of the Nilwala Ganga about 100 mi. S.E. of Colombo by road. Pop. (1953) 27,641. In Portuguese and Dutch days Matara was an important trading centre; the Dutch built fortifications (Star fort) which can still be seen. It is a commercial centre and a railhead, being the terminus of the coastal railway.

MATARA DISTRICT is densely peopled (pop. [1953] 413,431) and has paddy fields and plantations of coconut, with some tea, rubber, cinnamon and citronella grass. It covers an area of 481 sq.mi. and stretches inland into hilly country.

(B. H. F.)

MATARÓ (anc. ILURO), a seaport of Barcelona province in Catalonia region, northeast Spain, is on the coast 29 km. (18 mi.) N.E. of Barcelona by road. Pop. (1960) 41,128 (mun.). The church of Sta. Maria has a baroque altar and fine paintings. There is a museum and a public library. The first railway in Spain was built between Barcelona and Mataró (1848). The line now continues to Gerona, Port-Bou and France. Wine, carnations and potatoes are produced and exported. There are manufactures of hosiery and underwear, knitting machinery, soap, paper, chemicals and bus and truck bodies. Nearby is the carbonated mineral spring of Argentona.

(R. H. CA.)

MATCH, a splinter of wood, strip of cardboard or a length of waxed thread provided with a combustible tip that ignites by friction.

A match consists of three basic parts: a head, which initiates combustion; a tinder substance to pick up and transmit the flame; and a handle. There are two main types of modern friction matches: (1) strike-anywhere matches and (2) safety matches. The head of the strike-anywhere match contains all the chemicals necessary to obtain ignition from frictional heat while the safety match has a head that ignites at a much higher temperature and must be struck on a specially prepared surface containing ingredients that pass ignition across to the head. The substance com-

monly used for obtaining combustion at the temperature of frictional heat is a compound of phosphorus or one of its allotropic forms. This substance is found in the head of strike-anywhere matches and in the striking surface of safety matches.

In addition to the phosphoric igniting agent, three other main groups of chemicals are found in the match: (1) oxidizing agents, such as potassium chlorate, which supply oxygen to the igniting agent and the other combustible materials; (2) binders, such as animal glue, starches and gums, which bind the ingredients and are oxidized during combustion; an increasing interest was being shown early in the second half of the 20th century in the use of synthetics for this purpose, particularly in countries such as Brazil where climatic conditions make the drying of natural adhesives difficult; post-combustion binders, such as ground glass, which fuse and hold the ash together, must also be used; (3) inert materials, such as diatomaceous earth, which provide bulk and regulate the speed of reaction.

HISTORY

The development of matches was preceded by centuries of experiment with many methods of fire making (*see* FIRE) but the production of fire by spontaneous chemical reaction was unknown until the 17th century. A variety of experiments continued until the friction match, introduced in the 19th century, provided a means of making fire that was pocketable, reliable, safe and speedy.

Early Beginnings.—In 1669 a Hamburg alchemist, Hennig Brand, discovered phosphorus (*q.v.*) and thus placed a highly combustible material at the disposal of other experimenters. Apart from the discovery by Robert Boyle in England in 1680 that fire was produced when sulfur-tipped splints were drawn through a pleat of coarse paper coated with phosphorus, no other major development took place for over a century, probably because of the difficulties in preparing phosphorus.

With early methods of fire production it was common to use specially made splinters tipped with some combustible substance, such as sulfur, to transfer the flame. An increased interest in chemistry led to experiments to produce fire by direct means on this splinter. Jean Chancel discovered in Paris in 1805 that splints tipped with potassium chlorate, sugar and gum could be ignited by dipping them into sulfuric acid. Later workers refined this method, which culminated in the "promethean match" patented in 1828 by Samuel Jones of London. This consisted of a glass bead containing acid, the outside of which was coated with igniting composition. When the glass was broken by means of a small pair of pliers, or even with the user's teeth, the paper in which it was wrapped was set on fire.

In the meantime, interest in phosphorus had reawakened. The "ethereal match," or "phosphoric taper," appeared in France about 1780. This consisted of phosphorus and a piece of waxed paper or thread sealed in a glass tube in which the oxygen had been used up. When the glass was broken and the contents withdrawn, fire was started. By 1786 an Italian living in Paris had brought out the "phosphorus box," a pack of sulfur-tipped wooden splints with a small bottle of phosphorus. A splint was dipped into the bottle and ignited by the decomposition of adhering phosphorus upon withdrawal into the air. These methods were popular with those who could afford them and they continued in use until the friction match established its supremacy.

It is possible that phosphorus matches ignitable by friction were made in Paris as early as 1805; certainly a proposal by Derepas in 1809 to regulate the reaction of phosphorus by mixing it with magnesia lends credence to this. But the honour of making the first phosphorus friction match is usually granted to François Derosne of Paris (1816).

The Start of Industrialization.—Economic conditions between 1825 and 1835 appear to have favoured the manufacture of matches as an industrial proposition, although the first suppliers fell back on nonphosphoric formulas, *i.e.*, those based mostly on potassium chlorate mixtures. John Walker of England made a match of this type in 1827, although more serious production was undertaken in 1829 by Samuel Jones, who in the preceding year

had patented the "promethean match." Nonphosphoric friction matches were being made by G. E. Merkel of Paris and J. Siegal of Austria, among others, by 1832, by which time the manufacture of friction matches was well established in Europe.

These first matches were extremely difficult to ignite, and they frequently erupted in a shower of sparks. In addition, the smell was particularly offensive and the warning printed on Jones' box ("Persons whose lungs are delicate should by no means use Lucifers") seems well founded.

The first step in making matches that were both stable and easy to ignite was taken in 1831 by Charles Sauria of France, who evolved a satisfactory method of incorporating white (yellow) phosphorus into the formula to replace other oxidizable ingredients. As his principle was not patented, the next few years saw the introduction of white phosphorus matches throughout Europe. In the U.S. a patent was granted to A. D. Phillips as early as 1836, though Ezekiel Byam is usually acclaimed as the industrial pioneer. However, interest in nonphosphoric formulas continued until phosphorus established a clear lead.

Safety Matches.—An important milestone was the discovery of red phosphorus by Anton von Schrötter in 1845. Since red phosphorus is nontoxic and not subject to spontaneous combustion in air, it was of immediate interest to matchmakers. The idea of making matches intrinsically safe by placing some of the combustion ingredients on the striking surface of the box was first put forward by Gustaf Pasch of Sweden in 1844, although it is sometimes credited to B. Bottger of Frankfurt, who appears to have thought of the principle a year later. A manufacturing method making use of red phosphorus and the principle of separating the combustible ingredients was patented by J. E. Lundström of Sweden in 1852. Licences were taken out and other formulations prepared so that by 1856 matches of this type were being manufactured in several European countries.

Strike-Anywhere Matches.—Although the new safety match was widely accepted, white phosphorus matches continued to be used for many years since they had good keeping qualities and were relatively unaffected by climatic conditions.

The poisonous nature of white phosphorus was found to have serious effects on the health of workers in match factories. Phosphonecrosis, or phossy jaw (*see MOUTH: Diseases*), resulted when fumes entered the body through decayed teeth. Because white phosphorus was a danger to health and also was a fire threat since it burns spontaneously at 30° C. (86° F.) in moist air, many countries, starting with Denmark in 1875 and Sweden in 1879, introduced legislation to ban white phosphorus matches. As a result of a convention held at Bern, Switz., in 1905-06, white phosphorus matches were prohibited in the major countries of western Europe after 1912; in the U.S., they fell into disuse about the same time because of taxes levied against them when suitable alternatives became available.

Phosphorus sesquisulfide, which is much less toxic than white phosphorus, was first prepared by G. Lemoine in 1864 but the substance was not investigated by the match industry until E. D. Caben and H. Savène, both employed in the French government match monopoly, filed a patent in 1898 for its use in strike-anywhere matches. Leaders of the industry in countries that still permitted the manufacture of strike-anywhere matches immediately obtained licences, which were subsequently made available to their competitors without charge; Bryant and May introduced the technique into Britain and the Diamond Match company pioneered its use in the United States. Even so, considerable difficulties were encountered and it was some years before a reliable product was evolved.

Range of Products.—With the general acceptance of the friction match, many types of heads were investigated and the experience of the long-established candle trade was drawn on to provide tinder substance. However, economic considerations forced the matchmakers to use disagreeable materials, such as sulfur and resin, in their more competitive lines until the U.S. oil industry made mineral waxes available at prices everyone could afford. A wide variety of contrivances were made: e.g., sealing wax and candles were crowned with match heads, and

matches were made with heads at both ends and even in the middle. Because of fiscal requirements, market conditions and the availability of labour and raw material, only one or two types of matches are available in most countries.

20th Century.—Most of the changes made in matches in the first six decades of the 20th century were refinements of early details. One of the few innovations was the everlasting match of F. Ringer of Austria, Z. Földi and R. König of Hungary, and the Swedish Match company during the 1930s; its promise, however, was never realized.

MODERN TYPES OF MATCH

Household, Kitchen or Standard Matches.—These consist of the ignition head, tinder (made by soaking the splint nearest the head in paraffin wax) and the handle (the unsoaked portion of the splint). The splints are usually treated with some retardant, such as ammonium phosphate, to prevent afterglow when the match is extinguished. This type of match occurs in a wide range of box and splint sizes.

Vesta Matches.—These have short sticks in relation to their cross-section. They were originally made from wax and are generally regarded as smokers' matches.

Double-dip or "Bird's Eye" Matches.—These are commonplace on the North American continent as a form of strike-anywhere match, although in Europe they are restricted to the quality markets. A bulb of combustible material is interposed between a fast-ignition head and the tinder of the stick; they combine high sensitivity with safety in transport. The construction enables a smaller quantity of igniter to be used and the safety factor is increased since the igniter is kept from contacting the adjoining tips by the insensitive bulb below it.

Wax Matches.—These matches, which are popular in Latin countries, have their ignition head on the end of a short length of wax taper formed from paper or cotton filaments. The whole stick is therefore tinder. As they are difficult to extinguish, they are not permitted in certain countries because of the danger of starting fires.

Book Matches.—Matches of this type are made by stapling a comb of wood or cardboard matches inside a cardboard cover. Their method of burning is the same as a standard match. Wooden combs are more popular in continental Europe, while cardboard combs are used in the English-speaking countries. Book matches are used as an advertising medium, especially in the U.S., and the popularity of the book match stems entirely from its suitability for this purpose, which is much influenced by fiscal considerations from country to country.

Pyrotechnic Matches.—Commonly called "Bengals," these have a tinder substance below the head that is designed to burn with a bright flame tinted with one of the characteristic colours of metallic salts. The splint serves as a handle only.

"Lifeboat" and "Windproof" Matches.—Matches of this type share a common design and are similar to "Bengals." The tinder substance, which is spread along the splint below the head, produces a more positive reaction than the combustion of wood and paraffin wax, with the result that it cannot be extinguished by wind or water spray. Such matches may be subdivided into "fuses," in which the tinder substance burns strongly without flame (although ignition may be passed on), and "flamers."

Waterproof Matches.—As both the common match and the striking material on the side of the box are hygroscopic, many attempts have been made to make them waterproof. However, the more successful the proofing, the higher the cost and the more difficult the ignition. Use of waterproof matches is therefore restricted mainly to the armed forces.

MANUFACTURE

Splint Manufacture.—This procedure involves three main techniques. Square or oblong splints are made by peeling wood veneer (usually poplar or pine) in a lathe to the thickness of one dimension and chopping it on a separate machine to the other two dimensions. Splints that are round or crescent-shaped in cross-section are limited to the American market and are made

by forcing circular dies through soft pine blocks of thickness equal to the length of match to be produced. Wax splints are made by drawing paper or cotton filaments through a succession of wax baths and die plates until the requisite thickness is built up. The search for a suitable synthetic material for splints had not met any commercial success by the mid-1960s.

Box Manufacture.—In most areas of the world, the standard match box consists of separate inner and outer cases. An exception is the so-called "flap" box common to many Latin countries. In Europe, South America and the east, boxes are usually manufactured from wood and cardboard components held together by paste and paper. This type of box has not been widely used in the U.S., where the availability of suitable cardboard, coupled with high labour costs, encouraged the use of a one-piece component generated at high speed from a reel. Paul Dietmann in Sweden contributed much to the design of the European type of box, while the Diamond Match company developed the American style box. After World War II Bryant and May in England, and Arencio in Sweden, developed an American style of box adapted to European conditions.

Match Machines.—In the early days of the industry, match splints were dipped in the head composition by holding them in rows between slats in a hand frame. William Gates, Jr., of the U.S. patented a machine in 1854 that mechanized the handling of these frames and also made circular splints.

An outstanding early worker was A. Lagerman of Sweden, who in 1864 was operating a continuous match machine that embodied the principles used today. Also notable were R. Czerweny of Austria and G. Sebold of Germany. But it was the Diamond Match company of the U.S. that, early in the 20th century, first mass-produced a continuous match machine; it was based on the earlier designs of McClintock Young and was suitable for any climatic conditions. However, the machine did not keep pace with market conditions and went out of production, although in many parts of the world models of the machine were still in use in the 1960s.

Modern machines include an endless belt made up of metal bars suspended by chains in which the match splints or combs are carried from the feeding station to a hot plate to dry the tips. After this they are successively dipped in molten paraffin wax and ignition composition. If "bird's eye" matches are to be made, a second dipping station is provided, after a gap to ensure partial hardening of the first dip. The matches are then dried and dropped in controlled numbers into boxes, which are subsequently closed and packed. The trend after World War II was to integrate all manufacturing operations, including boxmaking and packing, into one unit capable of producing 40,000 boxes an hour.

Book matches are made in a very similar manner. When these are made from cardboard, the comb is cut from a reel at the feeding station of the match machine; when the matches are dry they are carried to a separate booking machine where the cardboard cover is folded round and the whole stapled. These machines can produce 600 books per minute. A separate process enables the cover design to be changed without stopping the match machine.

The bulk of the world's machinery for producing household matches is manufactured in Sweden, but book-match machinery is made in many countries.

MATE (PARAGUAY TEA), the dried leaves of *Ilex paraguariensis* (and some other species), an evergreen shrub or small tree belonging to the same genus as the common holly. Native names include *hierba* (yerba) mate and *hierba del Paraguay*. The leaves are from 6 to 8 in. long, shortly stalked with a somewhat acute tip and finely toothed at the margin. The small white flowers grow in forked clusters in the axils of the leaves; the sepals, petals and stamens are four in number, or occasionally five; and the berry is 4-seeded. The plant grows abundantly in Paraguay, and the south of Brazil, forming woods called *hierbales*.

Although mate appears to have been used from time immemorial by the Indians, the Jesuits were the first to attempt its cultivation. This was begun at their branch missions in Paraguay and the province of Rio Grande de San Pedro, where some plantations still exist, and yield the best tea that is made. From this circumstance the names Jesuits' tea, tea of the Missions, St. Bartholomew's tea, etc., are sometimes applied to mate. Under cultivation the quality of the tea improves, but the plant remains a small shrub with numerous stems, instead of forming, as in the wild state, a tree with a rounded head. From cultivated plants the leaves are gathered every two or three years, that interval being necessary for restoration to vigorous growth.

An open space, called a *tatacuá*, about six feet square, is prepared in which the surface of the soil is beaten hard and smooth with mallets. The leafy branches of the mate are then cut down and placed on the *tatacuá*, where they undergo a preliminary roasting from a fire kindled around it. An arch of poles, or of hurdles, is then erected above it, on which the mate is placed, a fire being lighted underneath. After drying, the leaves are reduced to coarse powder in mortars formed of pits in the earth well rammed. Mate so prepared is called *caa gazu* or *yerva do polos*, and is chiefly used in Brazil. In Paraguay and the vicinity of Paraná in Argentina, the leaves are deprived of the midrib before roasting; this is called *caa-miri*. A very superior quality, or *caa-cuys*, is also prepared in Paraguay from the scarcely expanded buds. Another method of drying mate has been adopted, the leaves being heated in large cast-iron pans set in brickwork, in the same way that tea is dried in China.

The tea is prepared in a small silver-mounted calabash, the tapering end of which serves for a handle. In the top, there is a hole and the tea is sucked by means of a *bombilla*. This instrument consists of a small tube six or seven inches long, formed either of metal or a reed, which has at one end a bulb made either of extremely fine basketwork or of metal perforated with minute holes, so as to prevent the particles of the tea leaves from being drawn up into the mouth. Some sugar and a little hot water are first placed in the gourd, the tea is then added, and finally the vessel is filled to the brim with boiling water, or milk previously heated by a spirit lamp. A little burnt sugar or lemon juice is sometimes added instead of milk.

Mate, like tea and coffee, contains caffeine, but in less quantity. It is also less astringent. Mate retains its flavour against exposure to air and dampness.

See R. H. Porter, "Mate—South American or Paraguay Tea," *Econ. Bot.*, 4:37-51 (1950).

MATERA, a city of the Basilicata region in southern Italy, chief town of the province of Matera, 27 km. (17 mi.) S. of Altamura by rail. Pop. (1961) 37,550 (comm.). The old part of the town is built on the slope of a deep ravine; the houses are cut in the rock in terraces, with only the façade built of stone. The modern part consists of normal dwellings. Important monuments are the Romanesque cathedral (13th century; rebuilt in the 19th century); and the churches of S. Domenico and S. Giovanni Battista (13th century); S. Agostino (16th century); and S. Pietro Barisano, carved out of the rock. The population is engaged in agriculture, tufa quarrying and the manufacture of terra cotta and artistic ceramics.

The origin of the town is obscure (it does not appear to be the Roman *Matteola*). It formed part of the duchy of Benevento and of the principality of Salerno and was occupied consecutively by

the Normans, the Aragonese and the Orsini. (M. T. A. N.)

MATERIAL CULTURE consists of tools, weapons, utensils, machines, ornaments, art, buildings, monuments, written records, religious images, clothing and any other ponderable object produced or used by humans. If all the humans in the world were to die simultaneously, nonmaterial aspects of culture would cease to exist; but the material culture would still be present until it disintegrated. It is in what L. A. White has termed the technological system that most of material culture is manifested. White's concepts of the sociological and ideological systems correspond in the main to what is meant by the term nonmaterial culture. The ideological (or philosophical) systems both affect and express technology and reflect the social systems which in themselves are functions of the technological systems. Authorities continue to debate whether material culture is dominant in molding nonmaterial aspects (see **SOCIAL ANTHROPOLOGY**); however it seems clear that its impact has varied from society to society.

Even under civilized conditions a great part of man's material culture is directly associated with the primary needs for food, shelter, clothing and protection. The classification of peoples or communities as hunters, pastoralists or farmers is therefore not without value.

It is probable that the first men to begin the cultivation of plants were neither hunters nor herders in a specialized sense, but food gatherers who, from depending upon such plant and animal produce as they could collect, were led to discover that roots and shoots and seeds could be made productive under control. Apart from such existing marginal peoples as pygmies (see **PYGMY**) who live by collecting, hunting and fishing alone, hunting may be a more or less essential activity in higher grades of culture, its importance decreasing with the extension of plant cultivation and animal husbandry, until in the higher civilizations it degenerates into a sport. The domestication of animals except as pets is in one way or another associated with agriculture. (See **ANIMALS**, **DOMESTICATION OF**; **AGRICULTURE**; **HUNTING AND FISHING**, **PRIMITIVE**.)

Hunting, fishing and agriculture may be regarded as specializations which arose out of the food gathering that was in the beginning the compulsory occupation of the human stock, as it is of the existing apes. Specialization in and dependence upon hunting involved a mode of life less likely to lead to and foster plant growing than would a more settled existence in an area where botanical food was plentiful, and where the phenomena of growth could be observed under similar conditions year after year. As is generally recognized, a settled life based on an abundance of food allows elaborations of culture that are impossible for nomadic hunters and fishermen. However, it was only when plant cultivation established itself as cereal culture—the growing of grain such as barley and wheat and maize, which could be stored for winter consumption—that the first civilizations became possible (see **AGRICULTURE**, **PRIMITIVE**).

Other primary needs such as clothing and shelter result in the invention of artificial environments without which man could not survive in nontropical habitats. The fur clothing of the Eskimo, for example, provides a warm bodily climate without which human life in cold regions is impossible. Without their bark-covered houses and an adequate supply of firewood the Huron Indians of Canada could not have survived northern winters. Ancient man could not have spread beyond the confines of warm climates without clothing and shelter (see **DWELLINGS**, **PRIMITIVE**).

Means of travel and transportation, especially over water and deep snow, were also very important since they played a necessary part in opening up new food areas and regions of possible settlement (see **TRANSPORTATION**).

A close study of the means of procuring food, obtaining clothing and shelter, and providing defense against enemies reveals innumerable weapons and devices for fighting, hunting and fishing; methods and appliances used in clothing and vehicle manufacture, plant cultivation and animal husbandry; and methods, implements and utensils for carrying, storing and preparing food. To these must be added, with considerable overlap, the tools and mechanisms used in the treatment of materials, and in the construction

of artifacts of all kinds. (See such articles as **WEAPONS**, **PRIMITIVE**; **HAND TOOLS**, **HISTORY OF**; **FLINT AND OTHER STONE TOOLS**; **TEXTILES**; **BARK CLOTH**; **WEAVING**; **SPINNING**; **BASKET**; **BOW AND ARROW**.)

To this core of material culture associated with primary needs must be added other items of material culture such as personal ornaments, objects of art, religious buildings, images of gods, religious and burial paraphernalia, instruments for measuring space, time and weight, games and musical instruments. Their nature is, indeed, determined by the state of culture with which they are associated and in their development they may react conspicuously upon the technique or construction principles; materials and habitat upon which they depend. (See such articles as **ARCHAEOLOGY**; **ART**; **ARCHITECTURE**; **POTTERY AND PORCELAIN**; **FUNERARY RITES AND CUSTOMS**; **SCULPTURE**; **MUSICAL INSTRUMENTS**; **GAMES [ARTICLES ON]**; **METROLOGY**.)

Culture Types and Culture Areas.—Particular cultures may be compared and contrasted with one another; those which are quite similar to each other may be grouped together to form a culture type. The cultures belonging to a culture type occupy and use a given territorial unit called a culture area. Usually in a culture area the technological aspect of culture interacting with the habitat is responsible for many of the similarities among the related cultures. For instance, one may speak of Plains Indians culture type or culture area (see **PLAINS INDIANS**). The chief natural resource of the North American plains region was the countless herds of buffalo grazing in the open grasslands. The buffalo was the staff of life for the typical Plains tribes and their cultures were a reflection of this fact. The people depended upon the buffalo for food, clothing, shelter and warmth. Their nomadic mode of life, concepts of warfare, social organization and religious ideas were elaborated in ways that were related to their primary dependence on the buffalo.

Ethnologists have described most, if not all of the culture types and culture areas of Africa, Europe, Asia, North America, South America, Australia and Oceania (*qq.v.*). Some culture types were of relatively brief duration whereas others persisted for a millennium or more.

Culture Change.—Culture is superorganic and superindividual; it is produced, participated in and carried by organic individuals, but it is transmitted from one individual, generation, age or group of people by social mechanisms without becoming a part of any individual's genetic endowment.

All cultures change by the addition and subtraction of trait elements, traits, types, complexes or configurations. All additive changes are innovations originating in a given culture by independent invention or by diffusion from one culture to another. In the realm of material culture such additions can be described in terms of form, material, use and technical principles. All subtractive changes are losses of what once were innovations. Any subtractive change can originate within a given culture or can be the product of diffusion.

Any cultural addition may or may not produce a corresponding subtraction. And if a subtraction does occur, it may be delayed for a considerable time. In North America, for instance, some Indian tribes in the Great Lakes region used bows and arrows for a hundred years after they had flintlock guns; there was a long period of innovation without corresponding loss. Among the same tribes, however, earthenware vessels of native manufacture disappeared from the cultural inventory at about the same time that brass kettles were supplied to them by French fur traders, a form of innovation by diffusion, with corresponding loss.

Culture change is required for culture growth or evolution; but there can be culture change without evolution.

Cultural Evolution.—Since evolution became a dominant motive in scientific studies, anthropologists have been guided by discoveries in archaeology as clues to the evolution of material culture. In modern civilizations there is a constant striving after discovery and invention. However, among early men, such developments were probably not so premeditated. It is reasonable to ascribe many of them to chance; for example, it seems unlikely that primitive man experimented with stones to produce fire

before he had observed sparks arising from chance percussion. But he must have soon lost this dependence on environmental suggestion. Thus, when he found he could make a new tool by thrusting a stone blade in the cleft of a stick, man opened a new field of invention. By variation, the bronze dagger emerged, later lengthened to become a sword. But important changes occurred as single steps of a more decisive character; e.g., the abrupt change from the worked stone held in the hand to one fixed in a wooden haft. Such steps of truly inventive nature have sometimes been called (as in biology) mutations. Most modern inventions are mutations that involve the adaptation of principles discovered in scientific research, or the adaptational transfer of a device or feature from one appliance to another.

In cultural evolution material culture plays an important role because so much of it is a manifestation of the technological system, the evolution of which is primary in the rise of civilization. The evolution of culture depends upon energy and the tools or machines which harness the energies. Primitive or unelaborated cultures depend upon human energy; the degree to which they can develop depends upon the type and efficiency of their tools and implements as well as their environments.

All civilization is based on the harnessing of plant energy in the form of cereals; thus civilization could only develop in environments suitable for agriculture and the growing of grains. With such energy at the disposal of man, subsistence was controlled. The more abundant supply of food increased the limits of population, allowed for the development of special skills and great specialization of labour, and permitted more people to live in one place, giving rise to cities and urban life. The society of precivilized cultures was based on ties of kinship and tribe (*qq.v.*). Populations were relatively small and the groups were unspecialized and not elaborated.

The society of civilized peoples was based on state and organized religion involving rulers, priesthoods, class systems, specialized labourers and artisans, and many other social and ideological forms that could only arise in relation to a well-developed agricultural technology. Western civilization had its first great revolution or radical change more than 8,000 years ago when the shift from food collecting to food producing (the agricultural revolution) was well under way. About A.D. 1800 the second great change in technology (the industrial revolution) took place; it was based on the harnessing of energy in the form of coal, oil, gas and heat as used in production of energy for engines. The harnessing of atomic energy has marked the beginning of the third great revolution in material culture and culture as a whole system.

See INDUSTRIAL REVOLUTION; ATOMIC ENERGY.

(H. S. H.; G. I. Qr.)

MATERIAL HANDLING. Since the beginnings of civilization, man has sought ways of moving objects which were too heavy or too bulky to be easily moved by himself. The use of mechanical devices to eliminate or simplify elements of human work has been termed mechanization, and material handling is that part of mechanization which is concerned with the transporting, positioning and storage of materials in industry.

The science of industrial material handling dates back to the late 18th and early 19th centuries. The use of an integrated system of belt conveyers for handling materials in a flour-processing mill was discussed by Oliver Evans in *The Young Mill-Wright and Miller's Guide* (1795). Bucket conveyers were employed in grain elevators as early as 1843, and overhead cranes were in limited use by 1850. By 1900, two-wheel and four-wheel industrial trucks were employed in industry for handling bags, drums and pans, and in 1913 the Ford Motor company established the first progressive assembly line for automobiles.

During World Wars I and II and in the intermediate period, the development of material-handling equipment progressed at a rapid pace. More and more, industrial plants adopted line-manufacturing methods in which whole processes were designed around the material-handling system. Although U.S. firms adopted mecha-

nized production systems more rapidly than those in other countries, considerable progress was made in all industrial areas of the world in replacing manual handling with mechanical-handling devices. In some cases, integrated systems of automatic processing equipment and material-handling equipment have produced completely automated processes which have eliminated the need for direct manual labour. Of course, skilled technicians are required to set up and maintain such complex manufacturing systems.

Since the handling of material does not usually contribute to its value, the moving, positioning and storing of product is always expensive, and one of the prime objectives of material handling is to lower handling costs. Various studies have shown that from 22% to 60% of total manufacturing cost may be attributed to handling materials. In addition, there are many indirect costs which may be affected by the procedures used for material handling, such as scrap material losses and machine delay losses. Other important objectives of good material handling are to (1) reduce production time; (2) aid in the control of the flow of materials; (3) reduce inventory quantities; (4) conserve plant floor space; (5) limit worker fatigue and prevent injuries; and (6) integrate handling and processing operations.

Selection of the proper handling equipment for a particular installation involves considerations of cost, reliability and suitability. For handling that involves area coverage, long hauls or changing flow patterns, industrial trucks or overhead cranes may provide the best solution; for fixed-path coverage, medium hauls or relatively stable flow patterns, conveyers may prove more satisfactory. The selection of a specific type of equipment requires detailed study of the product, the nature of the handling operation and the design of the manufacturing process in general. In selecting positioning or storage devices, product orientation or alignment may be another important consideration. Material-handling equipment may be classified as (1) conveyers, (2) hoists and cranes, (3) industrial trucks, and (4) unit-load accessories. Each type has certain defined areas of usage, although in many situations an integrated system of several different types of material-handling equipment is needed.

Conveyers.—The conveyer provides continuous, mechanized handling of material at any desired rate of movement. Conveyers may be operated intermittently or continuously, as desired, depending upon the type of drive mechanism provided. Conveyers will move anything from the lightest to the heaviest material, in almost any size, shape or condition and with a speed, accuracy and ease seldom achieved manually. The conveyer may serve solely as a movement device between points in the plant, or it may be an integral part of the manufacturing operation. It usually permits a reduction in work-in-process inventory, provides an excellent mechanism for controlling production and may serve as a ready-access, moving storage system. In addition to industrial applications, conveyers find many uses on farms and in other types of enterprise. Conveyers range in length from a few inches to an integrated system of conveyers several miles long. The major types of conveyers are gravity roller, gravity wheel, live roller, belt, floor, slat, flight, apron, vibrating, trolley, en masse, bucket, screw, pneumatic, tow, portable and transfer—each of which is briefly described below.

Gravity-Roller Conveyer.—Roller conveyers employ a series of parallel rollers of various diameters and materials which are supported at specified spacings in a metal frame and are used to convey objects and packages by gravity or manually (fig. 1). The

BY COURTESY OF CONVEYER EQUIPMENT MANUFACTURERS ASSOCIATION

FIG. 1.—ROLLER CONVEYER

conveyer frame sections may be placed directly on the floor, supported on fixed or adjustable-height legs, or supported on hangers from overhead structures. The frame sections may be straight or curved, and spirals, switches and crossovers are also available. Usually, several conveyer sections are joined together to form a system, and the system is inclined slightly if gravity flow of material is desired.

Gravity-Wheel Conveyor.—Wheel conveyers consist of a series of "skate" wheels mounted on parallel axles and supported at selected spacings between frame sections. They are used to convey packages and other flat-bottomed objects by gravity or applied manual force. They are similar to gravity-roller conveyers except that wheel conveyers are generally used for lighter loads and are comparatively less expensive. The use of wheels also limits the usefulness of the conveyor to specific handling jobs. The conveyor sections are available in both straight sections and curves and are supported like the gravity-roller conveyor.

Live-Roller Conveyor.—This type of conveyor is similar to the gravity-roller conveyor except that the rolls are power driven by means of a belt snubbed against the underpart of the rolls or by a chain driving sprockets attached to the rolls. Power may be applied to all or only a part of the rolls, and the driving medium may be of constant or variable speed. Live-roller conveyers are used to move materials in containers without the need for manual pushing or pulling and where the use of gravity is impractical.

Belt Conveyor.—Where it is desired to move packaged or bulk material, or even individual objects, on a continuously moving conveying medium, the belt conveyor is often selected. The belt may be of fabric, rubber, plastic, leather or metal, and is driven by a power-operated roll mounted underneath or at one end of the conveyor. The belt forms a continuous loop and is supported either on a metal slider pan or on rollers. In addition, suitable take-ups provide enough tension to keep the belt taut. The slider-pan support is used with flat belts when the load is sufficiently light to prevent a heavy frictional drag on the belt. For heavier loads, roller supports are always used. In some cases, the supporting rolls are mounted to form an angular trough in the belt, so that bulk materials can be carried in the cavity (fig. 2). Belt conveyers are generally laid out horizontally, but they can be operated at an incline if the material being carried is of such form that it will not slide back on the belt. For steeper angles of inclination, cleats may be mounted across the belt to prevent slippage of the material during rise or descent. Belt conveyers can be operated close to the floor on low supports, at table height with fixed or adjustable legs or at higher elevations when supported from the overhead structure. Power is generally provided by electric motors operating through a constant or variable-speed reduction gear.

Floor Conveyor.—This may be any of several types of conveyers using chain, cable or other linkage mounted in or close to the floor. Such conveyers are often designed to drag a series of four-wheel carts around in a horizontal loop, to carry large products or to permit assembly of products while on the conveying system. Power is supplied to the chain or cable, which operates within an endless track by means of guiding rollers. The material carriers are then attached with permanent or removable clamps to the conveying chain or cable.

Slat Conveyor.—Slat conveyers consist of one or more power-driven endless chains or other linkage, to which are attached spaced slats of various materials, to carry objects which would damage a belt because of weight or sharp edges and for which a live-roller conveyor would not be suitable. The parallel slats do not overlap and are not interlocking; they are attached to provide a continuous moving bed or platform. The chains or other linkage are driven by electric motors operating through suitable reduction gears and sprockets.

Flight Conveyor.—In this type of conveyor, scrapers or flights

of various materials are mounted at spaced intervals perpendicular to the direction of travel on one or more endless, power-driven chains operating within a trough. The flights are attached to the power-driven chain and serve to push bulk materials along the trough. These conveyers are designed in many different styles for handling sawdust, sand, gravel, stone, coal, chemicals and many other bulk materials.

Apron Conveyor.—When a continuous moving bed for bulk materials, packages or objects is desired, the apron conveyor may be the best solution. Overlapping and interlocking plates of various materials are joined to one or more endless chains to provide a continuous carrying surface which can be run either horizontally or up and down, as determined by the chain guides or supporting rollers. One of the main advantages of the apron conveyor is the "leakproof" bed which makes it suitable for bulk materials without containers (fig. 3).

Vibrating Conveyor.—The vibrating conveyor consists of a trough or tube which is flexibly supported and vibrated by mechanical or electrical means to convey objects or bulk materials. Vibration is in an inclined, elliptical pattern to cause directional as well as upward movement of the material. Since the conveyor has no moving parts other than the drive mechanism, it is particularly suitable for abrasive bulk material.

Trolley Conveyor.—Designed to carry objects and materials in containers from overhead supports, the trolley conveyor utilizes an overhead rail carrying a series of load-bearing carriers or trolleys which are coupled together on an endless propelling medium such as chain, cable or other linkage (fig. 4). Trolley conveyers provide an extremely flexible handling system, in that the rail may be installed to provide both straight and curved horizontal travel as well as inclines and twists. This type of conveyor is used with hooks, magnets or various carriers designed for the particular load to be handled. The trolley conveyor is particularly suitable for long moves between fixed locations, for in-process storage of material between operations, for special processes such as painting, baking and degreasing and for assembly work during movement. The rails are usually supported by the overhead structure of the plant building.

En Masse Conveyor.—This type of conveyor employs a series of skeletal or solid flights mounted at spaced intervals on a chain or cable which is power driven within a closely fitting casing. It is primarily designed for bulk materials which must be enclosed during transfer to prevent leakage or explosion. The conveyor can operate in horizontal, vertical or inclined positions, and it moves the bulk material in a continuous stream within the casing.

Bucket Conveyor.—The bucket conveyor consists of one or more strands of endless chain, belt or other linkage to which are attached buckets of various shapes and sizes, spaced at regular intervals, to convey bulk material in horizontal, inclined and vertical paths (fig. 5). The buckets remain in the carrying position until they are tipped to discharge the material. The

FIG. 5.—PIVOTED BUCKET CONVEYER

bucket conveyer can be used with or without a casing and can be designed with several different types of discharging mechanisms.

Screw Conveyer.—Screw conveyers are essentially a revolving shaft with continuous or broken spiral flighting which operates within a casing to convey materials along a prescribed path. The screw is usually designed to operate in only one direction and is powered by an electric motor and suitable gearing. Screw conveyers are particularly suited to fine bulk material such as meal, seeds and coal.

Pneumatic Conveyer.—Pneumatic conveyers move bulk material in tubes or ducts by means of air pressure or vacuum. Objects can also be handled by enclosing them in a cylindrical sleeve which closely fits the internal diameter of the pipe and is conveyed by the air pressure. Vacuum systems are used for drawing light bulk material from railway cars or bins, and the system works very much like a household vacuum cleaner.

Tow Conveyer.—Either the overhead trolley conveyer or the floor conveyer can be adapted for use as a tow conveyer. The cars or four-wheel carts are locked in to the towing chain or cable to move them from any one point in the system to any other point. Tow conveyers are used for handling many different types of dollies, trucks and cars. When the cars are disconnected from the towing conveyer, they may be used as storage devices or moved manually to any location in the plant. The towing system is usually provided with a variable-speed drive to permit flexibility in its use.

Portable Conveyer.—Any type of conveyer which is mounted on mobile supports, usually wheels, may be considered portable. Gravity-roller and wheel conveyers and short belt conveyers are particularly adaptable to portable use.

Transfer Conveyer.—This term has been applied to the intermittent transfer equipment which is utilized in the automatic transfer machine. It may consist of either a rotary indexing table or a straight-line indexing device which moves work-holding fixtures from one work station to another within one basic machine. The transfer device is a form of conveyer which is incorporated within the machine itself, and the machining heads are mounted onto or around the conveyer. (See also ELEVATOR.)

Hoists and Cranes.—These devices are used for lifting and lowering material and for limited area movement. The hoist is primarily a lifting device, the common types being chain, air and electric.

The chain hoist is manually operated. The air or pneumatic hoist employs compressed air to operate a cylinder or air motor and provide the lifting force. The electric hoist, which utilizes an electric motor for power, is the most economical unit for rapid lifting and lowering. In addition, the range of lifting capacities is greater for electric hoists than for air hoists and electrical outlets may be more readily available. However, air hoists are generally considered to require less maintenance. Fig. 6 illustrates a typical electric hoist.

A special type of hoist is known as the skip hoist. It is a motorized hoist having bucket cars which operate on steeply inclined rails. The skip bucket moves up and down the rails by means of a wire rope or chain, driven by a sprocket or drum at the head end. Skip hoists are used for elevating bulk material or parts for delivery into bins, mixers, grinders, etc., and may be either fixed or portable.

Cranes permit both vertical and horizontal movement of material within the limitations of their travel area. The more common industrial types are the portable, jib, gantry and bridge cranes,

all of which are discussed in more detail in a separate article (see CRANE).

Industrial Trucks.—The industrial truck provides intermittent movement of unit loads of material from any point in the plant area to any other point. A unit load is that amount of material which is grouped together for handling as one load. Industrial trucks provide maximum flexibility in making moves within the plant area, and they permit rapid, mechanized handling of all material which can be handled as a "load." Most of the many types of industrial trucks also permit mechanized pickup and deposit of these loads, thus eliminating manual work in lifting as well as in carrying.

Industrial trucks may be classified as hand trucks or power trucks depending upon the means of locomotion.

Hand trucks may, in turn, be classified by the number of wheels and by usage and general design. In general, two-wheel hand trucks permit most of the load to be carried on the wheels, but a portion of the load must be supported in the hands of the operator in order to balance the truck during movement. Some of the more common two-wheel hand trucks are the barrel, box, drum, hopper, refrigerator, paper-roll and tote-box trucks. Four-wheel hand trucks are found in many more varieties, including dollies, high- and low-bed flat trucks, carts, rack carriers, wagons and a number of different types of hand-lift trucks. The latter have mechanical or hydraulic lifting mechanisms for raising and lowering a load preceding and following transport.

Power trucks, as the name implies, have a power drive for locomotion. The use of such trucks in industry dates back to 1906, when electric drives were applied to ordinary baggage trucks at a Philadelphia railroad station. Power is supplied by (1) a gasoline engine and mechanical drive; (2) a gasoline engine, generator and electric-motor drive; or (3) batteries and an electric-motor drive.

Propane and diesel engines are also used in place of gasoline engines on some types of trucks. The common types of powered industrial trucks are the nonlift platform, low-lift platform, high-lift platform, fork, motorized pallet, side-clamp lift, ram, crane, tractor, straddle and side-loading trucks.

Nonlift Platform Truck.—One group of industrial power trucks is designed purely for hauling. A platform is provided on the truck for the load, which may consist of pans, packages or other

BY COURTESY OF YALE & TOWNE

FIG. 6.—ELECTRIC HOIST

BY COURTESY OF BIG JOE MANUFACTURING CO., INC.

FIG. 7.—LOW-LIFT PLATFORM TRUCK

objects. The nonlift platform truck is used to haul heavy loads over longer distances than would be desirable for a hand truck. In most cases, the operator rides on the truck with the load.

Low-Lift Platform Truck.—This type of power-operated truck is self-loading and provides a low platform for use with skids and certain types of metal boxes. These boxes provide a space for entrance of the platform and the front wheels of the truck. Since the front wheels ride under the load, the truck does not require counterbalancing and therefore heavier loads can be handled for a given size truck than with a fork truck. Capacities of these trucks vary from 2,000 to 10,000 lb. and more (fig. 7).

High-Lift Platform Truck.—Similar to low-lift platform trucks, the high-lift trucks are able to stack material. Both low-lift and high-lift platform trucks are available in "walkie" units, in which the operator walks and guides the truck, and in "rider" units, in which the operator rides on the truck. Walkie trucks have capacities up to 4,000 lb.; rider trucks range up to capacities of 60,000 lb. The maximum stacking height for high-lift platform trucks is approximately 130 in. High-lift platform trucks are also self-loading and are used with skids and boxes which permit the platform and front wheels to run under the load. This type of truck is sometimes employed to handle heavy press dies and large tooling. Some types of walkie platform trucks provide outrigger arms which contain the front wheels and go around the load rather than under it. In most cases, a hydraulic cylinder is used as the lifting mechanism.

Fork Truck.—The fork truck, which first appeared around 1927, is either a low-lift or high-lift, self-loading truck equipped with forks to handle loads on pallets, the elevating mechanism permitting multiple-tiering in the case of the high-lift models. The pallet is a load carrier of wood, metal or both, specifically designed to be picked up by and carried on the forks. The load is supported on a cantilever principle, with the rear of the truck being heavily weighted to balance the overhanging load. The fork carriage is supported on two upright masts which may be either rigid or permit tilting backward and forward for easy handling of the load. The masts on some models telescope to permit stacking up to 16 ft. Capacities of these trucks range from 1,000 to 60,000 lb. (fig. 8).

BY COURTESY OF ALLIS-CHALMERS MANUFACTURING CO.

FIG. 8.—FORK TRUCK

Motorized Pallet Truck.—This is another walkie truck, but with forks rather than a platform. It is particularly designed for use in narrow aisles, for moving and stacking loads which are too heavy for a hand truck. Motorized pallet trucks may be counterbalanced, like a fork truck, or they may have outrigger arms with front wheels like the platform truck. Capacities of these trucks range up to 4,000 lb. and may provide telescopic stacking to 130 in.

Side-Clamp Lift Truck.—Side-clamp lift trucks are similar to fork trucks except that the forks are replaced with hydraulically actuated side clamps, thus eliminating the need for a skid or pallet for many types of loads. Side clamps are available in several different designs for handling paper rolls, drums, stacked crates and boxes, bales, etc. In some cases a revolving head is

BY COURTESY OF CLARK EQUIPMENT CO.

FIG. 9.—STRADDLE TRUCK

provided so that the load may be turned over while supported in the clamps. One type of side-clamp truck employs hydraulically expanded rubber cushions to lift tile or brick stacked in unit loads.

Ram Truck.—Similar to the fork truck, the ram truck has a single protruding ram or fork for handling coils of sheet, wire or other coiled material. These trucks are constructed for heavy loads and may have several front wheels back of the ram to support weights of up to 100,000 lb. For lighter loads, a standard fork truck can be used by removing one of the two forks. Both ram and fork trucks are often driven backward, particularly when empty, to avoid serious injuries to workers in the area.

Crane Truck.—This truck consists of a portable boom crane mounted on an industrial truck, and it is used with hooks, grabs and slings for handling bundled or coiled material.

Tractor.—The tractor is essentially a mobile towing vehicle, used with four-wheel carts to make up a trackless train. It is usually co-ordinated with other facilities for loading and unloading.

Straddle Truck.—The straddle carrier closely resembles a gantry crane mounted on four pneumatic-tired wheels. The operator rides above the inverted U frame, within which the load is carried on elevating shoes. These trucks are used to handle lumber, bar steel and pipe. The size of the load can be as large as 108 in. high by 100 in. wide and as heavy as 30,000 lb. (fig. 9).

Side-Loading Truck.—This is a special design which combines features of the platform and fork-lift trucks. The platform portion of the truck has a centrally located well or bay in which is mounted the fork-lifting mechanism. These trucks are useful for picking up and carrying long, bulky loads.

Unit-Load Accessories.—Unit loads may be composed of individual items, grouped together and handled without breaking bulk, or of items which are held together by strapping, gluing or other physical means. The two most important unit-load accessories are skids and pallets.

There are three types of skids used in industry: live skids, which are dollylike carriers with wheels or casters; semilive skids, which have two wheels and two rigid supports; and dead skids, with runners or four rigid supports. Skids are handled by either two-wheel jack trucks or manual- or power-lift trucks.

Pallets usually have three stringers which, with single-platform pallets, act as supports and with double-platform pallets, as separators between the two platforms. Compared with skids, pallets are lower—usually about six inches over-all, with four-inch vertical openings to admit the forks. Double-faced pallets can be obtained for two-way, four-way or even eight-way fork entrance. Pallets are handled by fork trucks, pallet hand trucks or lift trucks adapted with forks. MATERIALISM, in philosophy, the view that all facts (including facts about men's minds and wills and the course of human history) are causally dependent upon physical processes, or even reducible to them. The many materialistic philosophies that have arisen from time to time may be said to maintain one or more of the following theses: (1) that what are called mental events are really certain complicated physical events; (2) that mental processes are entirely determined by physical processes (e.g., that "making up one's mind," while it is a real process that can be introspected, is caused by bodily processes, its apparent consequences also really following from the bodily causes); (3) that mental and physical processes are two aspects of what goes on in a substance at once mental and bodily (this thesis, whether called "materialistic" or not, is commonly opposed by those who oppose materialism); and (4) that men's thoughts and wishes influence their individual lives, but that the course of history is determined by the interaction of masses of men and masses of material things, in such a way as to be predictable without reference to the "higher" processes of thought and will.

Materialism is thus opposed to philosophical dualism or idealism and, in general, to belief in God, in disembodied spirits, in free will or in certain kinds of introspective psychology. Materialistic views insist upon settling questions by reference to public observation and not to private intuitions. Since this is a maxim which scientists must profess within the limits of their special inquiries, it is natural that philosophies which attach the highest importance to science should lean toward materialism. But none of the great empiricists have been satisfied (at least for long) with systematic materialism.

Materialistic Schools.—The Greek atomists of the 5th century B.C. (Leucippus and Democritus) offered simple mechanical explanations of perception and thought—a view which was condemned by the Socrates of the *Phaedo*; in the 17th century Thomas Hobbes and Pierre Gassendi, inspired by the Greek atomists, used materialistic arguments in defense of science against Aristotle and the orthodox tradition; and in the next century the materialists of the Enlightenment (Julien de Lamettrie, Paul d'Holbach, etc.) attempted to provide a detailed account of psychology.

In the 19th century the battle moved to new grounds. In the first place, some thinkers were encouraged by the theory of evolution to hope that, just as human life had grown out of animal and plant life, so these in turn might be explained as products of the simplest forms of matter; others, however, for instance C. Lloyd Morgan, later came to hold that new properties "emerged" in evolution—properties not fully explicable in terms of their antecedents (see EMERGENCE).

The question of materialism was thus merged into problems of method and interpretation in science (Henri Bergson, Samuel Alexander, A. N. Whitehead). Secondly, Georg Hegel, Auguste Comte, Karl Marx and others raised the question of the explanation of human history. Here Marx offered a new kind of materialism, dialectic and not mechanistic, and embracing all sciences—a materialism which alone retains its full vitality and coherence (see MARXISM).

In the 20th century other systems had to face novel developments in the sciences and in philosophy. In physics, relativity and quantum theory modified, though they did not abandon, the notions of cause and of universal determinism. In psychology, J. B. Watson's behaviourism, an extreme form of materialism, did not find general acceptance; and researches both in psychology and in psychoanalysis made it impossible to hold any simple direct view of the mind's dependence on the brain and the nervous system. At the same time experiments in psychical research showed (it was claimed) that mental events might have almost any kind of independence of bodily events. In philosophy, further reflection on the concepts of science and of common sense (especially those of cause and of explanation) suggested to many that it is futile to try to erect a system of belief whether materialistic or otherwise, on such a basis. See BODY AND MIND; IDEALISM; see also references under "Materialism" in the Index.

MATERIALS, STRENGTH OF, is that part of engineering science which deals with the behaviour of solids under the influence of forces which are in equilibrium. The forces may be of mechanical origin such as gravity, inertia or fluid pressure or they may be electrical or magnetic. In statics and dynamics it is assumed that solids are rigid and do not suffer any changes under the influence of forces other than those of equilibrium or position. Strength of materials is concerned with the deformation and distribution of solids when forces are acting upon them without consideration of changes in equilibrium or position.

Most engineering products are subjected to forces under whose influence they must neither break down nor deform beyond certain relatively small permissible limits. Strength of materials enables the engineer to estimate the forces which can be safely imposed on a given structure or engineering component, or to choose the appropriate material for and determine the necessary dimensions of structures and components which have to withstand given loads without suffering effects deleterious to their proper functioning.

Strength of materials is involved also in engineering problems of a different kind. The design of machinery such as rock crushers and coal cutters for the breaking up of materials involves consideration of the mechanical strength of these materials. Machining processes such as turning, drilling and planing pose other problems falling within the province of strength of materials. Cold- or hot-forming processes for the production of metal parts such as pressing, extruding or forging involve the problem of determining the forces necessary to produce certain permanent changes in form, and this is yet another group of problems in strength of materials.

This article is divided into the following sections:

- I. Elasticity
- II. Experimental Stress Analysis
- III. Testing of Materials
- IV. The Problem of Failure
- V. Metal Physics
- VI. Survey and Outlook

I. ELASTICITY

The fundamental concepts used in strength of materials are those of the theory of elasticity. This is a branch of applied mathematics, and for a full account reference should be made to the special article ELASTICITY. For the purpose of this article only certain fundamental concepts of this theory will be considered.

Concept of Stress.—Consider a solid of any arbitrary shape upon which several forces, P_1, P_2, P_3 , are acting as shown in fig. 1, where these forces are in equilibrium so that the solid is at rest. If a cut such as A-A is now made, destroying the cohesion of the solid, the two parts would move away from one another because the forces acting on each of the two parts are now no longer in equilibrium. Since, prior to the making of the cut, the two parts did not move apart it must of necessity be assumed that forces are acting within the solid on the cut face which prevent this movement. The forces must, therefore, be of such a character that their resultant balances the forces applied to each of the two parts. These internal forces called into play by external forces acting on a solid will be distributed in some manner over the surface of the imaginary cut, and each unit of area of the internal surface will carry an appropriate proportion of the force. This proportion of internal force carried by unit area is termed the stress.

If the force which has to be balanced is P and the area over which the stress can be assumed to be distributed is A then the average magnitude of the stress at every point of the surface A-A will be equal to P/A . In general, the distribution of stress over the area of an imaginary cut will not be uniform, and it is one of the general problems of the theory of elasticity to determine the exact distribution of stress in the interior of a solid subject to external forces.

FIG. 1.—STRESSES DUE TO LOADS P_1 , P_2 AND P_3 ACTING ALONG LINE A-A OF SOLID BODY

If a solid instead of being divided by one cut into two parts is divided by a large number of cuts into many small cubes of unit volume, each of these cubes by the same reasoning will transmit a force on each of its six cube faces. These forces will not be acting at right angles to the cube faces but each of them can be resolved into three components of which one, the normal stress, is acting at right angles to the cube face, and two components, called shear stresses, are acting in the cube face. Since there are six cube faces there will be 18 such components. Those, designated X_x , X_y , X_z , Y_x , Y_y , Y_z , Z_x , Z_y , Z_z , are shown in fig. 2.

Equilibrium Conditions.

Considerations of equilibrium lead to certain relations between these 18 stress components which reduce their number to 6, of which 3 are normal stresses and 3 are shear stresses. Moreover, certain first-order partial differential equations containing the derivatives of the stress components with regard to a system of rectangular co-ordinates can be deduced from considerations of equilibrium and continuity, and these equilibrium conditions form one set of fundamental equations which must be satisfied by the solutions obtained for any stress problem.

These three equilibrium conditions in the absence of body forces—that is forces proportional to mass and acting on each cubical element—are obtained in the following form where X_x , Y_y , Z_z are the three normal components, and $X_y = Y_x$, $X_z = Z_x$, $Y_z = Z_y$ are the three shear stress components:

$$\frac{\partial X_x}{\partial x} + \frac{\partial X_y}{\partial y} + \frac{\partial X_z}{\partial z} = 0$$

$$\frac{\partial Y_x}{\partial x} + \frac{\partial Y_y}{\partial y} + \frac{\partial Y_z}{\partial z} = 0$$

$$\frac{\partial Z_x}{\partial x} + \frac{\partial Z_y}{\partial y} + \frac{\partial Z_z}{\partial z} = 0$$

(1)

Tensile and Compressive Stress; Triaxial and Plane Stress.—Consider a solid in the form of a fine wire AB (fig. 3) at the ends of which two forces P of equal magnitude but opposite direction are acting, trying to tear the wire apart. Such forces produce stresses over any cross section of the wire directed away from the area of the cross section, and such stresses are called tensile stresses.

Consider a short pillar or block (fig. 4) carrying at the top a load P ; an equal and opposite reaction will be produced in the base of the pillar resting on the foundations. The pillar is under the influence of two forces trying to shorten it, and in every cross section of the pillar at right angles to the forces, stresses will be produced directed toward the surface of the cross section. Such stresses are termed compressive stresses. The wire under tension and the pillar under compression

FIG. 2.—CUBICAL ELEMENT OF SOLID WITH STRESS COMPONENTS OF A GENERAL TRIAXIAL STATE OF STRESS ACTING IN THE CUBE FACES

illustrate two of the simplest types of stress distributions in solids. The stress at every point of the solid will be the same, and will be in the same direction. If a small cubical element is considered with its edges parallel to the applied forces, only one of the six stress components is acting; all the others will be zero. Such a state of stress is called a uniaxial state of stress. The more general case when stresses are acting on all six cube faces is a general triaxial state of stress.

If stresses are acting only on four of the six cube faces as in fig. 5, the number of stress components will be reduced from six to three and the problem is one of biaxial stress or plane stress.

In the wire under tension or the pillar under compression the state of stress is the same at every point. Such states of stress, and they need not necessarily be uniaxial, are termed homogeneous states of stress. In general, the state of stress in a solid will be nonhomogeneous; this means it will be different at every point, or mathematically speaking; the state of stress is a function of the co-ordinates.

Concept of Strain; Poisson's Ratio.

Under the influence of the forces P acting on the wire in fig. 3, the ends will be displaced to points A' and B' respectively.

If the original length of the wire AB was l and the stretched length A'B' is l' the extension of the wire by the force P is $\Delta l = l' - l$. If the material of the wire is perfectly homogeneous each unit length of wire will make an equal contribution to the total extension and the extension per unit length is $\Delta l/l$. This is called the longitudinal strain.

Exact measurements of the diameter of the wire before and after

FIG. 5.—CUBICAL ELEMENT WITH STRESS COMPONENTS OF A PLANE STATE OF STRESS

application of the load would reveal that as the wire lengthens the diameter diminishes. The longitudinal dilatation of the wire under the influence of the tensile forces P is accompanied by a lateral contraction. This lateral contraction per unit length of diameter will be only a fraction of the longitudinal strain, so that the volume of the wire will slightly increase. The ratio of lateral contraction to longitudinal extension is a constant for a given material and is termed Poisson's ratio, μ . Its value varies between 0.2 and 0.5 for different materials. If the value of Poisson's ratio approaches 0.5, as it does for cork, there will be no change in volume in consequence of stress.

Shear Strain; General Deformation; Compatibility.

The deformation produced by a general state of stress cannot be described in terms of dilatations and contractions alone. A square ABCD under the influence of shear stresses will deform into the rhombus ABCD' (fig. 6) much in the manner of cards sliding over each other in a pack. The deformation is described by the angle DBD', and this is called a shear strain. If, as before, a solid of arbitrary shape is divided into a large number of small cubes each of the cubes can in the most general case suffer dilatations or contractions in the directions of the three cube edges, and in addition each of the squares bounding the cube can suffer a shear strain so that the cube is deformed into a parallelepiped. The three dilatations in the directions of the co-ordinate axes and

FIG. 4.—COLUMN UNDER COMPRESSION STRESSES PRODUCED BY FORCES P

FIG. 3.—WIRE AB EXTENDS TO A'B' UNDER THE INFLUENCE OF FORCES P , PRODUCING TENSILE STRESSES

the three shear strains in the co-ordinate planes describe the deformation of the elementary cube completely, and if these six strain components are known as functions of the co-ordinates they are known at every point of the solid and the deformation of the solid is then fully described.

There is one important condition which must be satisfied by the strain components. If they were entirely independent from each other, each elementary cube might be deformed in such a manner that after deformation the cubes would no longer fit together without gaps and the continuity of the solid would be destroyed. In order to ensure the continuity of the solid after deformation the functions representing the strain components must satisfy a set of six second-order partial differential equations which are known as the compatibility conditions.

These six compatibility conditions are obtained in the following form where e_{xx} , e_{yy} , e_{zz} are the three normal strains and $e_{xy} = e_{yx}$, $e_{yz} = e_{zy}$, $e_{zx} = e_{xz}$ are the three shear strains:

$$\begin{aligned} \frac{\partial^2 e_{xx}}{\partial y^2} + \frac{\partial^2 e_{yy}}{\partial x^2} - \frac{\partial^2 e_{xy}}{\partial x \partial y} &= 0 \\ \frac{\partial^2 e_{yy}}{\partial z^2} + \frac{\partial^2 e_{zz}}{\partial y^2} - \frac{\partial^2 e_{yz}}{\partial y \partial z} &= 0 \\ \frac{\partial^2 e_{zz}}{\partial x^2} + \frac{\partial^2 e_{xx}}{\partial z^2} - \frac{\partial^2 e_{xz}}{\partial x \partial z} &= 0 \\ \frac{\partial}{\partial x} \left(\frac{\partial e_{xy}}{\partial z} + \frac{\partial e_{xz}}{\partial y} - \frac{\partial e_{yz}}{\partial x} \right) - 2 \frac{\partial^2 e_{xy}}{\partial y \partial z} &= 0 \\ \frac{\partial}{\partial y} \left(\frac{\partial e_{yz}}{\partial x} + \frac{\partial e_{xy}}{\partial z} - \frac{\partial e_{xz}}{\partial y} \right) - 2 \frac{\partial^2 e_{yz}}{\partial x \partial z} &= 0 \\ \frac{\partial}{\partial z} \left(\frac{\partial e_{xz}}{\partial y} + \frac{\partial e_{xy}}{\partial x} - \frac{\partial e_{xy}}{\partial z} \right) - 2 \frac{\partial^2 e_{xz}}{\partial x \partial y} &= 0 \end{aligned} \quad (2)$$

The compatibility conditions can be derived from the fact that the components of strain are derivatives of the components of the displacement vector. The displacement vector is a measure of the displacement of each cubical element in space with regard to a fixed system of co-ordinate axes. If the components of the displacement vector in the three directions x , y , z of the co-ordinate system are designated by u , v , w respectively, the components of strain are derived as follows:

$$\begin{aligned} e_{xx} &= \frac{\partial u}{\partial x} & e_{xy} &= \frac{\partial u}{\partial y} + \frac{\partial v}{\partial x} \\ e_{yy} &= \frac{\partial v}{\partial y} & e_{yz} &= \frac{\partial v}{\partial z} + \frac{\partial w}{\partial y} \\ e_{zz} &= \frac{\partial w}{\partial z} & e_{zx} &= \frac{\partial u}{\partial z} + \frac{\partial w}{\partial x} \end{aligned} \quad (3)$$

The compatibility conditions can be derived from these six equations by eliminating the three components of the displacement vector. These six equations are therefore equivalent to the compatibility equations and are frequently used in their place.

Relation Between Stress and Strain; Proportionality; Elasticity.—It is a fact of experience that a wire subjected to equal and opposite forces P at its ends (fig. 3) extends. The extension is considered a consequence of the stresses produced in the wire by the forces. There exists, therefore, a relation of cause and effect between stress and strain, or strain can be considered a function of stress. This functional relationship must be expressible by some mathematical law, and two distinct possibilities for

postulating such a law present themselves.

The one possibility would be to determine the relationship experimentally and then find a mathematical expression representing this relationship. This meets with formidable difficulties because such measurements are possible only for relatively simple states of stress and deformation and cannot be carried out for general states of deformation resulting from triaxial states of stress. Measurements on metal wires and metal pillars, however, show that for certain simple types of stress, when the stresses do not exceed certain limits, the strain is proportional to stress so that a linear relationship holds.

For other metals and materials such as concrete, stone or timber, the relation even for simple states of stress is not linear. Such empirical stress-strain relations could of course only be applied with confidence within the region for which they have been experimentally confirmed.

The second possibility, and this is the one adopted in the theory of elasticity, is to postulate a relationship which will result in a mathematical theory aesthetically satisfying and at the same time simple. Only the assumption of a linear law permits this.

Robert Hooke published an anagram in 1678 embodying a discovery of his made in 1676. The solution of the anagram, "cciiioossttuu," when published two years later (*De potentia restitutiva*), expressed proportionality between stress and strain *ut tensio sic vis* (vis), "the power of any spring is in the same proportion with the tension thereof" where, as Hooke explains, spring means any "springy body" and tension is used for what is now called strain.

This law of proportionality has to be generalized for triaxial states of stress, and six equations can be written expressing the six strain components as linear functions of stress. This would involve 36 constants of proportionality.

The proportionality between stress and strain does not involve elasticity, this being the property of the solid to recover its original shape completely after the forces producing the deformation are removed. Elasticity on the other hand does not necessarily require proportionality between stress and strain. Modern spring steels, the most perfectly elastic materials known, recover their shape completely after deformation but stress and strain do not obey even approximately a linear law. Despite these fundamental conceptual differences between stress-strain proportionality and elasticity, the two concepts are used indiscriminately in such a way that elasticity implies proportionality and vice versa. The theory of elasticity paradoxically is in fact not primarily concerned with elasticity, that is, with the behaviour of solids after removal of the load, but is essentially employed as a linear theory with proportionality when the load is applied.

The assumption of elasticity, however, permits the application of certain thermodynamic principles which enable the reduction of the 36 independent elastic constants to 21. This number can be further reduced to 15 and if it is assumed that the material is isotropic with regard to its elastic properties, the number of elastic constants can be reduced to 2. These are the modulus of elasticity, generally denoted by the symbol E , and Poisson's ratio, μ , which has already been mentioned. The modulus of elasticity E is also called Young's modulus after Thomas Young who first defined it. It is for a given material the ratio between stress and strain for a simple uniaxial state of stress. Isotropy with regard to elastic properties means that the properties of the material are independent of direction. This is far from being true for most engineering materials. It is obviously not so for wood, which will exhibit different properties along the grain and across the grain. Metals produced by casting, rolling, forging or extrusion, however, will also exhibit some directionality with regard to elastic properties.

The six equations of proportionality or Hooke's law for a general triaxial state of stress are obtained in the following form:

Strains expressed in terms of stresses

$$e_{xx} = \frac{1}{E} [X_x - \mu(Y_y + Z_z)] \quad e_{yy} = \frac{1}{E} [Y_y - \mu(X_x + Z_z)]$$

$$e_{yy} = \frac{1}{E} [Y_y - \mu(X_x + Z_z)] \quad e_{zz} = \frac{1}{E} [Z_z - \mu(X_x + Y_y)] \quad (4a)$$

$$e_{xx} = \frac{1}{E} [X_x - \mu(Y_y + Z_z)] \quad e_{yz} = \frac{1}{G} Y_z$$

In these equations G is introduced as a further elastic constant, the modulus of rigidity. This, however, is not a third independent constant but is a function of Young's modulus and Poisson's ratio; i.e.,

$$G = \frac{E}{2(1+\mu)}$$

Stresses in terms of strain

$$X_x = 2G \left(e_{xx} + \mu \frac{e}{1-2\mu} \right) \quad X_y = G e_{yy}$$

$$Y_y = 2G \left(e_{yy} + \mu \frac{e}{1-2\mu} \right) \quad X_z = G e_{xz} \quad (4b)$$

$$Z_z = 2G \left(e_{zz} + \mu \frac{e}{1-2\mu} \right) \quad Y_z = G e_{yz}$$

In these equations

$$e = e_{xx} + e_{yy} + e_{zz} \quad (5)$$

is the change in volume of the unit cube of the material under the given state of stress, the cubical dilatation.

For a hydrostatic state of stress for which the three normal stress components $X_x = Y_y = Z_z$ are equal to a uniform pressure p and the three shear stress components $X_y = X_z = Y_z = 0$ the cubical dilatation from summation of equations (4a) is obtained as

$$e = \frac{1-2\mu}{E} p = k p \quad \text{where } k = \frac{1-2\mu}{E}$$

and k is called the modulus of compression or bulk modulus of the material. It follows from this relation that the value for μ cannot exceed 0.5 since for values of μ greater than 0.5 the bulk modulus becomes negative, which would require the solid to increase its volume under hydrostatic pressure.

Principal Stresses and Strains; Invariants and Strain Energy.—The six stress components describing the state of stress and the six strain components describing the state of strain at every point are of course functions of the co-ordinate axes and will change if a different co-ordinate system of co-ordinate axes is used. They form what are called tensors in mathematics, and from this fact one can make two important deductions with regard to the effect of transformations of co-ordinate axes.

The first is that there are always three orthogonal directions for which, when they are chosen as the co-ordinate axes, the expressions for the shear stresses and shear strains become zero and for which the values of the normal stresses are extreme values. These directions are the directions of principal stress or strain and the largest of the three principal stresses or strains will be the absolute maximum value of the stress or strain at the given point and the smallest of the three will be the absolute minimum value. If the state of stress or strain is written in the form of a matrix; i.e.,

$$\begin{pmatrix} X_x & X_y & X_z \\ Y_x & Y_y & Y_z \\ Z_x & Z_y & Z_z \end{pmatrix} \quad \begin{pmatrix} e_{xx} & e_{xy} & e_{xz} \\ e_{yx} & e_{yy} & e_{yz} \\ e_{zx} & e_{zy} & e_{zz} \end{pmatrix}$$

then for the three principal directions $x \rightarrow 1 \rightarrow y \rightarrow 2 \rightarrow z \rightarrow 3$ the state of stress will be fully characterized by three principal stress components

$$\begin{pmatrix} X_1 & 0 & 0 \\ 0 & Y_2 & 0 \\ 0 & 0 & Z_3 \end{pmatrix}$$

and the state of strain by three strain components

$$\begin{pmatrix} e_{11} & 0 & 0 \\ 0 & e_{22} & 0 \\ 0 & 0 & e_{33} \end{pmatrix}$$

In the case of simple tension or compression already discussed the direction of the tensile or compressive stress will be a direction of principal stress because the shear stresses in planes at right angles and parallel to this direction must be zero.

The equations of equilibrium (1), the compatibility conditions (2) and the equations of proportionality (4a, 4b) can be written in terms of principal stresses without losing generality.

In tensor analysis, which is that branch of mathematics dealing with tensors, it is shown that certain expressions can be formed from the components of tensors of the type used for the description of states of stress or strain which are invariants with regard to transformations of co-ordinate axes. These invariants must clearly be representative of some intrinsic properties of the stressed solid since only such properties can be entirely independent of the system of co-ordinate axes and this is the second important deduction to be considered. The first of these invariants for stress and strain are

$$I_1^s = X_x + Y_y + Z_z$$

$$I_1^e = e_{xx} + e_{yy} + e_{zz} \quad (5a)$$

The first of these expressions indicates that the sum of the three principal stresses is a constant. The second of these two expressions is the cubical dilatation and this, as expressing the change in volume, must clearly be independent of the co-ordinate axes.

The following two expressions are further invariants for the two tensors:

$$I_2^s = X_x Y_y + X_x Z_z + Y_y Z_z - X_x^2 - Y_y^2 - Z_z^2 \quad (5b)$$

$$I_2^e = e_{xx} e_{yy} + e_{xx} e_{zz} + e_{yy} e_{zz} - e_{xx}^2 - e_{yy}^2 - e_{zz}^2$$

They have no physical meaning in themselves but an expression obtained by combining the two invariants (5a) and (5b) either for stress or strain has a physical meaning and must, of course, itself be again invariant. Thus the expression

$$U = \frac{E(1-\mu)}{2(1+\mu)(1-2\mu)} (I_1^s)^2 - \frac{E}{1+\mu} I_1^e \quad (6)$$

is invariant and must represent a physical property U , the strain energy per unit volume of the strained solid. Work is required to be done against the resistance of the body by the external forces in deforming it. This is stored in the form of the elastic energy which is released when the loads producing the deformation are removed. The unwinding of a clock spring is perhaps the best example illustrating stored strain energy.

A similar expression for U can, of course, be derived in terms of stress components by combining I_1^s and I_2^s . This is in fact the form in which strain energy is mostly used. Evaluated in a convenient form the expression (6) becomes

$$U = U_1 + U_2 \quad (7a)$$

$$U_1 = \frac{1-2\mu}{6E} (X_x + Y_y + Z_z)^2 \quad (7b)$$

$$U_2 = \frac{1+\mu}{6E} [(X_x - Y_y)^2 + (Y_y - Z_z)^2 + (Z_z - X_x)^2] + \frac{1}{2G} (X_y^2 + X_z^2 + Y_z^2) \quad (7c)$$

The first part U_1 of this expression is that part of the strain energy which is absorbed by changing the volume of the solid. The second part U_2 is called the shear strain energy or energy of distortion. It is that part of the total strain energy which is absorbed by a pure change in form without any change in volume. Considerations of strain energy play an important part in the solution of many problems in the theory.

Application of Elastic Theory.—The equilibrium conditions, the compatibility conditions and Hooke's law form the fundamental system of equations which must be solved for given boundary conditions in order to determine stresses and strains at every point of a solid subject to given external forces. This undertaking is, even in relatively simple cases, a formidable mathematical one and is possible only by the use of fairly extensive mathematical apparatus and manipulation. Even then solutions are generally obtainable only if certain a priori assumptions are made with regard to the stress distribution or the deformation to be expected which simplify the problem.

Since two dimensions are more easily handled than three, most problems of a practical nature are reduced to problems of either plane strain or plane stress. In the first case it is assumed that the deformation is entirely confined to two directions so that no change in dimensions of the solid takes place in a direction at right angles to the plane of the co-ordinate axes, or at any rate that this change in dimension is a constant. In the case of plane stress problems it is assumed that the object is flat and that stresses can only act on it within its own plane and not at right angles to it. It is certainly no exaggeration to say that hardly ever is a general solution found of a strength of materials problem by producing general solutions without a priori assumptions. In this fact alone lies a severe limitation of the scope of the theory of elasticity. Most solutions involve certain a priori assumptions and are therefore at best approximations. Most of the approximate solutions that have to be used by the engineer are crude in the extreme, though little benefit can be derived by more accurate solutions obtainable only by prodigious labour, because the scope of the theory of elasticity is far too restricted to give in any case more than approximate solutions. This is true because the actual behaviour of materials deviates widely from that assumed in the theory of elasticity. For the exact numerical solution of two-dimensional problems step-by-step methods have been developed, primarily by R. V. Southwell; these are known as relaxation methods.

In order to illustrate the character of approximation made where exact methods are too complex, a simple case will be considered, that of the bending of a beam, which is in itself important.

Bending of Beams.—If a load P (fig. 7[A]) is acting on a beam resting on two supports A and B, reaction forces R_A and R_B will be produced at these two supports which can be determined from the conditions of equilibrium of the beam considered as a rigid body. Equilibrium in the direction of the load P requires that

$$R_A + R_B = P \quad (8)$$

and if the beam under the influence of the three forces P , R_A and R_B is not to rotate, the moments of the forces about any point must be zero. Take for instance moments about point B.

$$R_A \times l + P \times b + R_B \times 0 = 0 \quad (9)$$

From this $R_A = -\frac{Pb}{l}$ and R_B from

$$\text{equation (8) gives } R_B = -\frac{Pa}{l}.$$

If an imaginary cut is now made at say ED and the equilibrium of the length of beam DB is considered (fig. 7[B]), a force S equal and opposite to R_B ($S = -R_B$) must act in the cross section in order to prevent translatory movement. This, however, would cause the beam DB to rotate, and in order to prevent the rotation a couple or moment $M = R_B \times DB$ must be assumed to be acting in the cross section as well. This moment is called the bending moment acting in the cross section, and the force S is called the shear force.

Bending moment M and shear force S must be produced by internal stresses in the cross section and the problem is to find the distribution of these stresses. This problem can be solved laboriously by solving the general equations (1), (2), (4) considered previously for the particular boundary conditions of the problem. If, however, one makes the a priori assumption that each of the cross sections of the beam including DE deforms in such a way under the influence of the stresses resulting in the bending moment M that it remains a plane cross section, the problem is greatly simplified.

The cross section DE will turn through a small angle $d\phi$ relative to another cross section FG a small distance dx away from it

FIG. 6.—BENDING OF BEAM. (A) ROTATION OF CROSS SECTION DE BY ANGLE $d\phi$ RELATIVE TO CROSS SECTION FG; (B) LINEAR DISTRIBUTION OF BENDING STRESSES OVER CROSS SECTION DE; (C) ROLLED STEEL JOIST IN CROSS SECTION

A simple calculation gives the stress

$$X_s = \frac{Mxy}{I_s} \quad (10)$$

where I_s is the second moment of area or moment of inertia of the cross section with regard to the axis z at right angles to x and y . The moment of inertia is a simple geometric property of the cross section. It is easily calculated as the integral $I_s = \int y^2 dy ds$ and its value will depend on the size and shape of the cross section. The bending stress X_s is a maximum at the extreme fibres and zero at the centre. This region of zero stress coinciding in the present example with the axis of the beam is called the neutral axis.

The maximum value for the bending stress is obtained by substituting the boundary value $\frac{d}{2}$ for y in equation (10) where d is the total depth of cross section. Hence

$$\text{Max } X_s = \frac{M \frac{d}{2}}{I_s} = \frac{M}{Z} \quad (11)$$

where

$$Z = \frac{I_s}{\frac{d}{2}} \quad (12)$$

The value Z is called the modulus of the section and this, like the moment of inertia, is a geometrical property of the section.

It is obvious from equation (11) that the maximum stress X_s decreases as the value of Z increases. For a given weight, sections of the form shown in fig. 8 (C) where the material is concentrated as far away as possible from the neutral axis have larger Z values than other possible shapes, and it is for this reason that rolled I sections are generally used as metal beams. They are fabricated in standard sizes and their values of I and Z are tabulated.

The distribution of the shear force S has to be considered next. If a narrow slice of the beam at the section DE is produced by making a second cut FG at a small distance away from DE (fig. 9), the shear forces S will be acting on the two sections in opposite directions (fig. 9[B]). If the cross section of the beam is assumed rectangular of depth d and width b (fig. 9[A]), one can consider the slice DE divided into a number of small cubes as shown in fig. 9(C) and if as a first step one considers the shear force uniformly distributed over the cross section, each cube would

carry a fraction of the shear force equal to $\frac{S}{db}$ and the shear deformation of each cube would be the same as shown in fig. 9(D). It will be noted that this deformation still leaves the plane cross sections DE and FG plane. This uniform distribution of shear stress, however, is impossible because it would require shear stresses, which can only occur in pairs for reasons of equilibrium, to act in the surface elements EG and DF. These elements, however, since no force is acting in the surface, must be free from

(fig. 8[A]). This requires that the material near point D becomes longer and the material near point E shortens. These changes in length, equal to the strain in the x -direction ϵ_{xx} —if we assume the direction of the x -co-ordinate axis coinciding with the axis of the beam—multiplied by the original length dx of each element are proportional to the distance y of the element from the axis of the beam, and since the stresses are proportional to strain, these too will be distributed linearly over the cross section as shown in fig. 8(B).

The resultant of this stress distribution which is antisymmetrical with respect to the x -axis is a moment, the bending moment M .

FIG. 9.—RECTANGULAR BEAM: (A) CROSS SECTION; (B) SHEAR FORCES S ACTING IN ADJACENT CROSS SECTIONS DE AND FG ; (C) LINEAR DISTRIBUTION OF SHEAR STRESSES; (D) DEFORMATION DUE TO LINEAR DISTRIBUTION OF SHEAR STRESSES; (E) PARABOLIC DISTRIBUTION OF SHEAR STRESSES; (F) DEFORMATION DUE TO PARABOLIC DISTRIBUTION OF SHEAR STRESSES. CROSS SECTIONS DE AND FG WARPED

stress. The uniform shear distribution is, therefore, impossible and the next simple assumption that can be made is a distribution obeying not a linear law but a square law (see fig. 9[E]). The shear stresses are distributed in accordance with a parabolic law, so that the shear stress at the neutral axis is a maximum and that at EG and DF is zero. If the deformation resulting from this shear distribution is now considered (fig. 9[F]), it will be seen that the elementary cubes at EG and DF remain entirely undeformed, whereas the elementary cube situated at the neutral axis is deformed most. The cross sections ED and FG , however, are now no longer plane but warped, and this is directly in contradiction with the assumption used in calculating the bending stresses, that plane cross sections remain plane.

This solution for the distribution of bending stresses and shear stresses obtained on the basis of simple a priori assumptions with regard to the deformation leads, therefore, to a contradiction of the original assumption of plane sections and can only be considered as an approximation to the true distribution of stresses over the cross section. It is, nevertheless, found to give reasonably good agreement with experience and observation and the linear distribution for bending stresses and the parabolic distribution for shear stresses are universally used in the design of beams subjected to bending loads.

Calculation of Deformations.—The same assumptions enable the deformations, in particular the curved form of the initially straight beam when it is deflected, to be determined simply. In this instance also the results of calculations are in good agreement with the results of measurements.

The calculation of elastic deformations is in fact one of the most important applications of the theory of elasticity. Whereas the usefulness of the theory is gradually diminishing in other fields, yet to be discussed, it is still of great importance to the engineer when the criterion for the proper functioning of the part is not primarily strength, but deformation.

Limits of deformation have to be imposed, for instance, on the deflections of beams in buildings, since if deflections were not limited, ceilings might sag, walls and glass might crack. To prevent this, it has been found from experience that beams should not be allowed to deflect by more than about $\frac{1}{300}$ part of the distance between supports.

II. EXPERIMENTAL STRESS ANALYSIS

There are many stress problems for which it is impossible to find mathematical solutions. Solutions for the simpler problems such as the one just discussed were worked out 100 years ago. More complex problems require formidable mathematical skill and labour and in many cases mathematical solutions cannot be found at all. Very often the form of the solid is such that the boundary conditions cannot be expressed in mathematical form; often simplifying assumptions that would permit solution are unjustifiable.

Numerous experimental methods have been developed, particularly after the first quarter of the 20th century, which permit the

determination of stresses and deformations by measurement. Of these the most important are: photoelasticity, analogy methods, strain measurements and brittle coatings.

Photoelasticity.—Transparent materials when under stress exhibit coloured patterns. This photoelastic effect, discovered by Sir David Brewster in 1816, can be used for the experimental determination of the stresses in transparent objects. Methods for this purpose, developed by E. G. Coker and L. N. G. Filon, have reached a high state of perfection and refinement.

A scale model of the object to be studied is made from a transparent synthetic resin such as Bakelite, Catalin, Araldite or Columbia resin; glass, Celluloid and gelatin which were used by the pioneers of this method are now rarely used. This model is mounted in the loading frame of the photoelastic bench and strained in such a way that the conditions of loading correspond to those expected in practice. Certain optical effects occur which are related to the direction and magnitude of the principal stresses in the model, and which are seen as coloured bands or alternatively bright and dark bands in the model when it is viewed through an analyzer. The analyzer is generally a disk of Polaroid, a plastic material having the property of polarizing light. The coloured bands or light and dark fringes, shown in fig. 10 for a plate with a circular hole, can be readily interpreted to give the directions of the principal stresses and their magnitude at every point of the model.

DEPARTMENT OF ENGINEERING, UNIVERSITY OF CAMBRIDGE

FIG. 10.—PHOTOELASTICITY. TRANSPARENT MATERIAL UNDER STRESS VIEWED IN POLARIZED LIGHT TO SHOW "INTERFERENCE FRINGES" FROM WHICH MAGNITUDE OF STRESS AT EACH POINT CAN BE DEDUCED. BLACK CIRCULAR AREA IS HOLE

The great value of the method lies in giving a visual image of the regions where the stresses are particularly high, that is, where so-called stress concentrations occur. Such stress concentrations are generally associated with abrupt changes in section and contour. Photoelasticity is a magnificent tool for evaluating such stress concentrations quickly and for obtaining exact information on the influence of alterations in form and contour on the magnitude of such stress concentrations. This evaluation is often quite impossible by mathematical analysis and even if it is possible, the amount of mathematical labour involved is prodigious.

Photoelasticity is primarily useful for plane stress problems, but recent developments permit the method to be used in the form of the "frozen stress technique" also for three-dimensional problems.

Analogy Methods.—These are generally based on the fact

that some problems in stress analysis lead to differential equations identical to those pertaining to some other physical problem which can be readily solved experimentally.

For instance, the stresses produced by twisting a bar are obtainable mathematically only if the cross section of the bar is circular or of some other simple geometric shape. There is, however, an analogy between this problem and certain geometric properties of a soap film stretched over the contour of the cross section of the bar and maintained under slight air pressure. The geometric properties of the soap film, such as the volume enclosed, the form of the contour lines and the gradients, can be determined relatively easily by measurement, and from such measurement the stresses in, and rigidity of, a noncircular component of a similar cross section subjected to twisting can be readily determined.

Strain Measurements.—A large number of special instruments have been developed which permit the strains experienced by a loaded solid to be measured directly on the surface. Since in most cases the maximum values for the stresses and hence the strains

occur in the surface of the loaded solid, this method permits the direct determination of the maximum value of stress from the measured strains by multiplication with the appropriate elastic constant.

Strains are, of course, extremely small quantities of the order of microinches per inch (10^{-6} in. per inch). The change in length of 1 in. of a steel bar subjected to the maximum value of stress that might normally be permitted to occur in an engineering component would be $\frac{1}{10,000}$ of an inch.

In regions of stress concentration, which are always the most important, the strains alter abruptly within short distances so that the gauge length of the instrument over which the total change in length is measured must be small. Instruments with gauge lengths of $\frac{1}{16}$ in. and less have been constructed. With a gauge length of $\frac{1}{16}$ in. a large strain of 10^{-3} would only be a change in length of $\frac{1}{16}$ of $\frac{1}{10,000}$ in. The measurement of such minute quantities requires that some principle of magnification is made use of in the construction of the instrument. Mechanical, optical, pneumatic, electrical and magnetic principles have been used for magnification in the design of such instruments.

The most ingenious and perhaps most widely used is the electric resistance strain gauge. This is essentially a small piece of thin paper to which a short length of fine wire is cemented. This piece of paper with the wire is glued to the object prior to the application of the load at the point where it is desired to know the stress. When the load is applied and the object deforms, the paper and the wire will suffer a strain equal to that of the object at the particular point. Now, if a fine wire is stretched, its electrical resistance will change because of its change in length and its change in cross section. This resistance change is proportional to the strain experienced by the object and can be accurately measured. An installation of electric resistance strain gauges in the interior of a pressure vessel to determine the stresses in the vicinity of a nozzle can be seen in fig. 11. Strain gauges also can be seen attached to the buckled cylindrical shell shown in fig. 22.

Methods of strain measurement, particularly by electric resistance strain gauges, have been found of particular value in the solution of dynamic stress problems. Where the conditions of loading change rapidly with time as would be the case in all parts of moving machinery or in the members of a bridge when a train passes over it, or in the wings of an airplane passing through a gust, the state of stress will change equally rapidly. In all such cases strain gauges have proved a valuable research tool and have permitted the solution of problems which, had they been left to mathematical analysis on the basis of theory of elasticity, would have remained unsolved.

Brittle Coatings.—If an object is coated with a lacquer or other substance which cannot suffer strains equal in magnitude to those suffered by the object, the lacquer will crack along lines at right angles to the direction of principal stresses, and a pattern of cracks in the lacquer will be obtained which can give a valuable indication of the direction of principal stresses, and from the density of the cracks conclusions with regard to the magnitude of the stresses can be drawn.

III. TESTING OF MATERIALS

The theory of elasticity permits the determination of the deformation of an object under load as long as these loads do not exceed certain limits. The deformation problem, however, is only one aspect of the engineer's strength problem. Far more difficult and far more important is the problem of failure. It might appear at first sight that the theory of elasticity aided by the powerful methods of experimental stress analysis would be equally effective in solving the failure problem.

Until comparatively recently the problem appeared simple enough. Since the stresses are calculated on the basis of the theory of elasticity, it was argued, the stresses must be limited to the maximum value of stress for which proportionality between stress and strain is maintained and for which the material behaves, in accordance with the theory, as an elastic body. In order to determine these limits it became necessary to test materials and to determine their mechanical properties such as the elastic constants,

BRITISH WELDING RESEARCH ASSOCIATION

FIG. 11.—INSTALLATION OF ELECTRIC RESISTANCE WIRE STRAIN GAUGES INSIDE A PRESSURE VESSEL TO DETERMINE STRESS DISTRIBUTION IN THE VICINITY OF A NOZZLE

Young's modulus and Poisson's ratio, the limit of proportionality, that is the maximum stress up to which proportionality between stress and strain is maintained, and the elastic limit, which is the maximum stress up to which elasticity is maintained. It was also interesting to determine to what extent the stress could be increased beyond the elastic limit before rupture occurred under different forms of loading. From such modest beginnings grew a whole separate branch of the science of strength of materials concerned with materials testing.

Originally, materials testing or mechanical testing was confined to the determination of mechanical properties under simple tensile or compressive loading. By the late 1950s the number of different mechanical tests was large. Whereas in the beginning mechanical testing was concerned with the determination of the limits within which elastic theory could be safely applied to engineering materials, it changed its character completely and largely became a method of quality control. In fact, many mechanical tests were no longer concerned with mechanical strength properties in the sense in which this concept logically arises in strength of materials, but with properties required in the fabrication of materials such as the property of a steel sheet to be deformed by deep drawing and pressing, or of a steel plate to be joined by welding.

Tensile Test.—The tensile test occupies a unique position among mechanical tests. This is an extremely curious phenomenon because the true significance of the so-called tensile properties is not easily interpreted. Nevertheless, engineers often judge a material primarily by its properties exhibited in the tensile test. It is simple and economical, it takes little time, it does not require much material or elaborate apparatus other than a tensile testing machine of which one can now be found in almost every metal-producing or metal-using factory. No elaborate or precision measuring equip-

ment is required and the test can be carried out by semiskilled or unskilled labour because the results can be autographically recorded. Tensile testing, like almost all material testing, is governed far more by simplicity, convenience, cheapness and expediency than by scientific requirements.

The tensile test is carried out with a prismatic or cylindrical piece of material of standardized dimensions. Its ends are clamped in the testing machine which applies a tensile load whose magnitude is increased from zero to its maximum value either slowly or sometimes, particularly in routine tests, fairly rapidly. By plotting the load against the extension of the test piece measured over a gauge length of several inches marked out along the test piece prior to the test, the load extension diagram of the material may be obtained.

The salient features of the diagram as shown in fig. 12 are these: from zero load to point A the diagram may closely approximate to a straight line. In this case the material has a proportional limit, the stress corresponding to point A. If the test were interrupted at or below this point and the load released, the specimen would be likely to resume its original length; that is, it would appear to behave with perfect elasticity, and the elastic limit would be found to coincide reasonably well with the limit of proportionality. In actual fact if sensitive methods of measurement were used it would be found on unloading that the specimen did not resume its original length but was left with a "permanent set," because no material exists which on first straining exhibits perfect elasticity. If, however, the test were continued to a point such as C it would be found that the rate of deformation now increased more rapidly than the rate of loading, and if the specimen were unloaded from a point such as C the unloading curve would not follow the original loading curve but would run parallel to the straight (elastic) part of the loading curve to D. The specimen would be found to have suffered a permanent elongation OD. This is called plastic deformation.

If the specimen were immediately reloaded the loading curve would follow the almost perfectly straight line from D to C and would then follow the curve CG as if no previous unloading had taken place. Unloading from point C, however, has raised the limit of proportionality of the material which had previously been at point A to a level corresponding to point C. The previous deformation increases, as it were, the resistance of the material to plastic deformation. This increase in resistance against plastic deformation by previous plastic deformation is known as work hardening.

If the test piece instead of being reloaded immediately were allowed to rest for perhaps several months and was then loaded again it would be observed that it had hardened even more. The resistance to plastic deformation might have been increased to a value corresponding to point E. This phenomenon is known as strain age hardening or strain aging. At the same time as the resistance to plastic deformation is raised the capacity of the material for plastic deformation is greatly reduced. Many of the modern aluminum alloys owe their high strength properties to this process of work hardening, which takes place during one stage of the manufacture when the material is shaped by processes, such as cold-rolling or extruding, which impose a large degree of plastic deformation.

If no unloading at any point takes place and the tensile test is completed without interruption the load will reach a maximum value at the point G (fig. 12). Up to this point the specimen will have extended fairly uniformly and the diameter will uniformly diminish because during plastic deformation virtually no change in volume takes place.

After reaching the maximum load, however, the cross section of

the specimen at one point diminishes rapidly and a kind of local narrowing down or necking takes place. Further plastic deformation is now confined to a relatively narrow zone in the neck and then fracture occurs suddenly.

The stress obtained by dividing the maximum load by the original cross section of the material is called the ultimate tensile strength of the material. If, however, the actual load at fracture (corresponding to point I, fig. 12) is determined, which is not easy because necking down and fracture may occur in fairly rapid succession, and if this load at fracture is divided by the greatly diminished cross section in the neck, a stress value is obtained appreciably larger than the ultimate tensile strength. This stress value is called the true fracture strength of the material. The method of plotting load against extension hides this fact. If, instead of load, true stress, obtained by dividing the load at any point during the test by the actual cross section corresponding to the load, is plotted against extension the true stress extension diagram is obtained and this is represented by the dotted line going to I' (fig. 12). The point I' represents the true fracture strength and it can be seen that this is larger than the stress corresponding to point H, the ultimate tensile strength. Nevertheless, it is not true fracture strength but the ultimate tensile strength of the material which has been considered by engineers as the most important mechanical strength property characterizing a material.

The total extension of the specimen consists of two distinct parts, O to H, the uniform extension, and the part from H to J, the necking extension. It is expressed as a percentage of the original standard gauge length and is known as the percentage elongation. For ductile materials such as some steels and some of the lower strength aluminum alloys, the percentage elongation may be 20% and more. For relatively brittle materials such as white cast iron or severely work-hardened materials the percentage elongation may be only 1%. Percentage elongation is considered as the most important property characterizing the ability of a material to be severely deformed although there are strong indications that the

percentage reduction of area, $\frac{A_0 - A}{A_0} \times 100\%$ (A_0 , original area,

A minimum area at fracture in the neck), is more valuable for this purpose.

Yield Point.—This brief outline of the tensile test could apply to every metal used in engineering except the most commonly used, mild steel or steel of medium carbon content. The load extension diagram of this material exhibits a curious but important anomaly. Soon after the limit of proportionality is exceeded and slight plastic deformation has set in, the material "yields," that is, it deforms rapidly at constant load; sometimes there is even a small drop in load before the rapid deformation. This drop is indicated by the horizontal step shown as a thicker line in the load extension diagram at point B in fig. 12. The load B at which yielding takes place is called the yield point of the steel. After yielding is completed, which is accompanied by an extension of between 0.5% and 1%, the material begins to harden and the remainder of the tensile test proceeds as described earlier.

The yield point is an important property of the material because it clearly defines a stress level at which the amount of plastic deformation begins to grow large. So useful has this been found that an artificial yield point has been defined for materials such as certain alloyed steels and light alloys which do not exhibit, as it were, a natural yield point. This artificial yield point is termed the proof stress and is defined as the stress for which there is a definite amount of permanent plastic strain after removal of the load. This is generally 0.1% or 0.2%, and one then speaks of the 0.1% or 0.2% proof stress.

The yield point of steel is of great importance because it has long been considered that the permissible or working stresses in structures and components, that is to say the stresses developed when the working loads are applied, should be kept well below the yield point.

The yield phenomenon is the basis of an extensive and relatively new subject of strength of materials: the theory of plasticity. This subject is concerned with the study of the behaviour of metals and

FIG. 12.—SCHEMATIC LOAD EXTENSION DIAGRAM OF A METAL

DEPARTMENT OF ENGINEERING, UNIVERSITY OF CAMBRIDGE

FIG. 13.—FRACTURE OF CONCRETE IN A COMPRESSION TEST

to some extent other substances such as concrete. For metals the theory of plasticity is of particular value. On the one hand a much more realistic approach than is possible by the theory of elasticity can be made to the problem of failure. On the other many problems arising in the plastic working of metals, such as forging, rolling and extruding, can be solved only by the new theory.

Compression Test.—This is one of many other mechanical tests. A test piece, generally in the form of a cube, a prism or cylinder, is compressed between the platens of a compression testing machine. Ductile metals such as mild steel will deform elastically up to a certain limit; then plastic deformations will occur, and the test piece, if the metal is ductile, can be completely flattened under increasing loads.

Brittle materials such as rock, brick, cast iron and concrete will fracture as shown in fig. 13 though they may exhibit great compressive strengths. Thus, the crushing strength of concrete determined by breaking a cube, and often called the cube strength, may reach values of three tons per square inch and more. Granite may reach 10 tons per square inch and cast iron from 25 to 60 tons per square inch.

Notch Impact Test.—There are various forms of this test. In one of them, the so-called Charpy V-notch impact test—and all notch impact tests are similar in character—a specimen in the form of a simply supported beam approximately 50 mm. long and 10 mm. by 10 mm. cross section, with a sharp notch of 2 mm. depth in the form of a 45° "V" machined in the middle of the underside, is broken by a sharp blow from a weight falling on the specimen. The energy absorbed by the specimen in fracturing is measured.

There is no way of relating results obtained in this test to any strength of materials concept based on the theory of elasticity. Nevertheless the test is most valuable and gives an indication of the toughness of the material under conditions of impact or shock loading. Under such impact conditions and in the presence of a notch producing stress concentrations, ductile and deformable materials may break in a brittle manner without absorbing much energy. A lowering of testing temperature has the same effect and the notch impact test is considered a valuable test for steels used in welded structures and exposed to low temperatures in service (see the section *Brittle Fracture*, below).

Hardness Test.—This is carried out by pressing with a given load a hard steel ball (Brinell hardness test), of standardized dimension, or a diamond ground in the form of a square pyramid mension, with an angle of 136° between faces (Vickers' pyramid hardness), into the surface of the material, and then measuring the dimensions of the impression. The harder the material the smaller will be the impression. There are several other forms of hardness test, all based on the same principle.

Fatigue Tests.—It is found that a metal and in fact most other materials can be broken by applying a smaller stress than that corresponding to its static tensile strength if this is applied not once, but many times. This phenomenon is called fatigue. The smaller the applied stress the larger is the number of cycles required to produce fracture, and if the stress is small enough fracture may not occur until the stress has been applied perhaps hundreds of millions of times.

The character and appearance of the fracture is different from that produced in a static test, at least for ductile metals. In the static test appreciable plastic deformation takes place before fracture supervenes; fracture as it were is preceded by a visible warning. No such warning precedes fatigue fracture. A microscopic, sharp crack is formed at some stage during the test which continues to grow until fracture occurs suddenly. There is no sign of deformation visible to the naked eye, the fracture surfaces exhibit a smooth appearance and are often characterized by prominent sea shell-like markings as can be seen in fig. 14 showing a fracture in a crankshaft due to fatigue. The two parts into which the fracture divides the object can be fitted together and match perfectly whereas the plastic deformation during a static test of the same object would so deform the fracture surfaces that the fractured parts would not fit together. This absence of visible deformation makes it appear as if the material was made brittle by the fatigue test. This is not the case. Brittle fracture, although somewhat similar to a fatigue fracture, is due to an entirely different mechanism.

Attempts have been made to deduce the strength of metals under the repeated application of loading, which is called the fatigue strength, from static strength properties and even in the late 1950s some engineers still believed that the fatigue strength of a metal could be assumed to be a definite fraction of the static strength. This, unfortunately, is not the case and the fatigue strength must

DEPARTMENT OF ENGINEERING, UNIVERSITY OF CAMBRIDGE

FIG. 14.—CRANKSHAFT FRACTURED BY FATIGUE

be determined by separate tests.

Special testing machines are necessary for the carrying out of fatigue tests. The machines must be capable of applying many loading and unloading cycles rapidly if fatigue tests are to be completed within a reasonable time, because unlike the static strength which can be determined with one test piece, the determination of the fatigue strength of a given metal requires several. There are many different types of fatigue testing machines, some of which can apply up to 10,000 stress cycles per minute.

The fatigue strength of a material is generally determined in the following way. The first specimen is subjected to cyclic variation of stress of constant amplitude until it breaks. Generally a fairly high value of stress will be selected for the first specimen so that fracture is obtained fairly rapidly. The number of cycles endured to fracture is plotted, say point 1 in fig. 15, against the value of the applied stress. Further specimens are tested in the same way but at smaller and smaller stresses and the results are plotted. In this way a diagram of stress versus number of cycles is obtained which is called the S-N diagram (fig. 15). This diagram tends for certain materials—particularly steels—to run more

and more parallel to the N-axis as the stress is reduced. It is concluded from this that there will be a maximum value of stress which could be applied infinitely often without producing failure, and this is termed the endurance limit or sometimes the fatigue limit of the material.

If such an endurance limit exists it will not be much smaller than say the stress which gives failure at 2,000,000 or 10,000,000 cycles, and in general fatigue tests are not carried to greater lengths. The stress for which failure occurs at 2,000,000 cycles or 10,000,000 cycles is determined and used as the mechanical property characteristic of the fatigue strength of the material.

For some other metals, particularly aluminum alloys, the S-N diagram does not become parallel to the N-axis so that one must assume the fracture in consequence of fatigue will supervene eventually however small the stress is. Fatigue tests ending in fracture have in fact been carried out up to 1,000,000,000 cycles.

Fatigue testing by the late 1950s had largely moved out of the field of material testing and was being established as a separate branch of strength of materials. The idea that fatigue strength is a mechanical property of the material, which can be determined basically in the same way as the yield point or ultimate tensile strength, has been abandoned because fatigue strength is influenced by far too many variables. Different values for fatigue strength of the same material will be obtained when it is tested in tension varying between zero and a maximum and when it is tested under some other form of cyclic loading such as equal limits of tension and compression or a cycle varying between two constant tensile limits.

The fatigue strength is also found to be strongly influenced by a whole host of other variables such as the form and surface condition of the specimen, the testing frequency, the type of stressing, either tensile or bending. Moreover, it is found that engineering components may quite readily fail from fatigue even if the maximum value of the stress is well below the endurance limit of the material as determined by tests on specimens of the metal. There is a size effect and numerous other circumstances have compelled engineers to look upon fatigue resistance as something more complex than a simple mechanical property which can be determined unequivocally by testing a few small specimens of the material.

IV. THE PROBLEM OF FAILURE

This brief survey of the testing of materials shows that the region in which materials behave in accordance with the pattern assumed in the theory of elasticity is narrow. The "solid" assumed in the theory of elasticity is in fact a structureless, homogeneous, stiff, but nevertheless jellylike substance, unlike any real solid, conforming to a certain behaviour pattern chosen for mathematical convenience and not for its correspondence to reality. The theory of elasticity in fact does not deal with solids but with regions of space of certain simple properties within closed boundaries. It is only natural that fracture or failure is quite outside its province. There is nothing in the theory of elasticity which would permit the introduction of the concept of fracture.

A solid could, of course, be conceived of perfectly proportional and elastic behaviour up to a maximum value of the stress when it would suddenly break; this maximum value of stress would then be the breaking strength of the material, but no such ideal material exists and the behaviour pattern of most materials used by the engineer is markedly different from this ideal pattern. Moreover, even if such materials existed an important problem would still arise.

In the elastic analysis of the state of stress produced for instance in a thin tube by twisting, it is found that on each element of the tube two stresses are acting: one a tensile stress and at right angles to this a compression stress of equal magnitude. If it is now assumed that the "fracture strength" of the ideal elastic solid had been determined for a simple state of uniaxial tensile stress, the problem arises how large the stresses in the tube may become

FIG. 15.—S-N (STRESS V. NUMBER OF CYCLES TO FRACTURE) DIAGRAM USED FOR PLOTTING RESULTS OF FATIGUE TESTS

before fracture occurs. Will fracture occur when the tensile stress reaches the same value as in uniaxial tension, the tensile fracture strength, or will the compression stress at right angles influence the magnitude of the fracture strength? The theory of elasticity by its very nature cannot answer a problem such as this because it is not concerned with fracture.

If the theory of elasticity does not permit the prediction of the stresses at which solids fail, in what way is it then possible to determine the loads which can be safely imposed on engineering structures and components? The answer to this important question is that, except in a few cases, these loads cannot be predicted on the basis of any theory; they can only be determined experimentally. It is obviously impracticable to design all engineering structures on the basis of tests to destruction though this method has been used for such large and important products as automobiles and airplanes.

The difficulty has been overcome in the past by a most plausible and ingenious piece of sophistry and self-deception, the "permissible stress." Since most engineering materials have a range in which they are almost elastic and in which strain is proportional to stress, the theory of elasticity could be assumed to represent actual conditions of stress accurately if the stresses were limited to permissible values not exceeding the proportional limit. If this is possible, fracture and failure need obviously not be considered. In fact, permissible stress methods of design were used by the majority of engineering designers not because the inherent flaws in the method remained unrecognized but because, with one or two exceptions, there was nothing more satisfactory to take their place.

There are four flaws in the permissible stress concept of which two are fundamental, the third is practical and the fourth economic.

The first flaw is similar in character to the difficulty of predicting the fracture strength of a solid under conditions of triaxial stress. The proportional limit stress of the material which the permissible stress is supposed not to exceed can be determined by experiment only for relatively few and very simple types of stress such as tension (tensile test), compression (compression test) and pure shear (twisting of thin tubes). A crankshaft, for instance, would be subjected in service to bending stresses, to shear stresses from the bending loads and to additional shear stress from the torque transmitted by the shaft. Each small element of the crankshaft would be subjected to a combination of stresses, what in fact has been previously referred to as a general triaxial state of stress. The problem is to define the proportional limit for triaxial states of stress from the experimentally determined proportional limits of uniaxial stress. This problem has been quite successfully solved by certain hypotheses which are discussed below, but a second problem remained.

The state of stress in the crankshaft is not uniform. The three stress components describing the state of stress vary from point to point, the question—impossible to decide—is which of these innumerable combinations of stress actually occurring at different points is the most dangerous. Will the proportional limit be exceeded first at the point where the bending stress is a maximum irrespective of the magnitude of shear stress, or where the shear stress reaches a maximum value, or where both bending and shear stress reach modest values? This aspect of the problem can still be overcome in some sort of fashion by introducing a "reference stress" which is calculated for any point by taking account of both shear and bending, though there are formidable practical difficulties in doing this.

There is, however, a third difficulty and this cannot be overcome because it is fundamental. The proportional limit is determined experimentally for states of stress which do not vary from point to point. In applying such data to states of stress which vary from point to point, the assumption is implicitly made that what happens at one point is determined only by the state of stress at that point irrespective of the state of stress at neighbouring points, which means that provided the state of stress at the point considered is not varied its proportional limit will also not be varied however drastically the state of stress is varied in neighbouring material. This assumption is known to be false—the behaviour of the metal at one point is dependent not only on the state of

stress at that point but is strongly influenced by the state of stress in the neighbouring material because certain deformation processes will only take place if an appreciable volume of the material is, as it were, ready to take part in this deformation. It follows that under most practical conditions the stress which can be permitted without exceeding the proportional limit is unknown.

The second flaw in the permissible stress concept is also fundamental. It is in fact virtually impossible to limit the stresses in an engineering component or structure to the proportional limit even if the value of this for complex stress conditions were accurately known. A simple example will make this clear.

Steel structures have for many years been assembled by riveting, which entails the drilling of holes in the members of the structure through which the rivets pass. It was known that the stresses in the immediate vicinity of a hole in a member under load may, by virtue of the sudden geometric discontinuity, reach three times the value which would have been found in the absence of the hole. Similarly the oil holes necessary in the crankshaft referred to earlier and the junctions between crank webs and pins represent geometric discontinuities which give rise to great, though purely local, increases in stress or stress concentrations. Few structures or engineering components have ever gone into service so devoid of geometric stress raisers that the stresses under working conditions were below the proportional limit. From this one can conclude that it is not really sound to base design on the limitation of the permissible stress to the proportional limit.

On the whole, with such exceptions as the all-welded ships which failed at low stresses during World War II, structures so designed have nevertheless given satisfactory service and it was realized that this is due to the ductility of most engineering materials. Once, however, it is conceded that limiting the permissible stress to the proportional limit does not necessarily result in safety, it follows that failure and fracture cannot be neglected, and this hard fact of experience is the third flaw in the permissible stress argument.

The fourth, economic, flaw in the argument immediately follows from the third. If in most cases the plasticity of the material is sufficient to protect a structure against failure despite the fact that stresses occur in excess of the proportional limit, the design based on such low stress values cannot be in fact as economical as it might be. If higher stresses than the proportional limit can obviously be sustained without harm under certain circumstances at points of stress concentrations, it might be possible to permit stresses in excess of the proportional limit far more generally by invoking deliberately the mechanism of plasticity for the whole of the structure or component. Such deliberate recourse to plasticity should afford much greater economy in design.

Consideration of failure could no longer be side-stepped by the artful dodge of limiting permissible stresses to the proportional limit. Adherence to these concepts not only leads to extravagance, it has other far more pernicious effects. On the one hand it stultified the development of structural design, and on the other it has forced the development of metal manufacture into directions which have not altogether proved fruitful and beneficial. In the manufacture of aluminum alloys in particular these outmoded and rigid concepts have led to the development of alloys of ever higher tensile strength which have proved disappointing under actual service conditions.

Modern endeavours are devoted to the development of methods which permit design to be based on actual conditions of failure. There are six primary conditions of structural or material failure which must be considered entirely separate. Which of these six has to be envisaged in design depends of course on the service conditions of the structure.

Structures and engineering components fail by (1) plastic failure; (2) instability; (3) fatigue; (4) creep; (5) corrosion; and (6) brittle fracture.

There may be other circumstances such as excessive wear but these six are responsible for almost all failures in industry and transport, and it is believed that fatigue alone accounts for 90% of service failures.

Plastic Failure.—Stress Concentration.—This type of failure

is extremely rare because plasticity is by its nature a protective mechanism. This can best be appreciated from a single example. Consider a bar of uniform rectangular cross section (fig. 16[A]) with two tensile loads P acting at the ends as in the tensile test. The stress distribution over any cross section such as A-A will be uniform, the stress being everywhere of magnitude S . If now a circular hole is made in the bar (fig. 16[B]) at the section A-A the stress distribution will be greatly changed. At the ends of the diameter B-B the stress will be increased to a value $S_k = Sk_t$, where k_t is a factor of 3 and is called the stress concentration factor for the circular hole. Other forms of geometric discontinuities will have a similar effect except that the numerical value of the stress concentration factor can be much larger or much smaller than that for a circular hole.

As the load is increased from P to P_1 the stress at points B will reach the proportional limit of the material, and soon after the yield point, if the material is mild steel. The stress distribution will then be that shown in fig. 16(C). Further increase in the load to P_2 (fig. 16[D]) cannot produce any further increase in stress at points B because the material there yields at constant stress and the increase in load must be absorbed by increased stresses on both sides of points B.

In this way increases in load will produce two zones of yielding starting from points B and moving outward toward the parallel edges of the bar. Eventually (fig. 16[E]) load P_3 will be reached for which the zones of yielding have reached the edges and every point of the cross section A-A carries a stress equal to the yield point of the material. The total load carried is, therefore, $A \times f_y$ where f_y is the yield point stress; this is the same load as would be carried by a bar with the same cross section A but no hole.

The mechanism of plastic deformation has protected the bar from the effect of stress concentration, so that in fact the load carried by the bar when it is loaded up to the yield point is only influenced by the presence of the hole insofar as the cross section is reduced. If it is assumed that a bar without a hole is perfectly safe as long as the stress does not exceed the limit of proportionality, one would obtain the cross section of the bar required

to carry a load P as $A = \frac{P}{f_p}$ where f_p is the limit of proportionality.

If it is further assumed that the proportional limit is 90% of the yield so that $f_p = 0.9, f_y A = \frac{P}{0.9f_y}$. If it is in order for the bar

without the hole of fig. 16(A) to carry this load it must necessarily be so for the bar of fig. 16(E) with the hole also, because at yielding there is no difference in the stress distribution of the bar of fig. 16(A) and that of fig. 16(E), so that for the perforated bar the

required cross section is also $A = \frac{P}{0.9f_y}$. On the basis of elastic theory and permissible stress the required cross section would be three times as great. This is because the maximum stress in

FIG. 16.—EFFECTIVE ELIMINATION OF STRESS CONCENTRATIONS BY PLASTICITY: (A) UNIFORM STRESS DISTRIBUTION IN A BAR OF UNIFORM CROSS SECTION UNDER THE INFLUENCE OF TENSILE LOADS; (B) STRESS CONCENTRATIONS AT THE EDGE OF A CIRCULAR HOLE; (C) MAXIMUM STRESS AT EDGE OF HOLE REACHES YIELD POINT OF MATERIAL WHEN LOAD REACHES VALUE P_1 ; (D) FOR LOADS BETWEEN P_1 AND P_2 STRESSES AT EDGE OF HOLE CANNOT INCREASE BEYOND YIELD POINT. ZONES OF YIELDING SPREAD OUTWARD; (E) THE ENTIRE CROSS SECTION AT YIELD POINT STRESS FOR LOAD P_3 .

the perforated bar, occurring at the surface of the hole and of magnitude three times that of the average stress P/A , would have to be restricted to the value of the limit of proportionality; i.e.,

$$\frac{3P}{A} = f_p \quad \text{or} \quad A = \frac{3P}{0.9f_y}$$

This illustrates the point made earlier that the same mechanism of plasticity which, more by accident than by design, protects structures against the effects of stress concentrations ignored in calculations, can be deliberately used in design to effect appreciable economies. The perforated bar in fig. 16(E) would be considered to have reached its maximum carrying capacity when the collapse load $A \times f_y$ was reached because large deformations would then be produced. It is important to realize that such a collapse load can be defined only for conditions of static loading, that is, loading which is applied relatively slowly and then remains constant. Applications of the theory of plasticity are, therefore, necessarily limited to cases of statically loaded structures. Unfortunately the theory had not been developed far enough, by the late 1950s, to be used in the design of all such statically loaded structures, but there was one group of structures for which the plastic method of design had reached a high degree of efficiency and perfection: the steel frame for buildings, which is essentially composed of mild steel beams and columns.

Plastic Theory of Beams and Frame Structures.—It was pointed out in considering the bending of a beam that every cross section is subjected to bending stresses which are linearly distributed over the cross section. Consider now what happens in that cross section of a simply supported beam (fig. 17(A)) where the bending stresses are largest, when the load and hence the bending moment is increased.

The bending stresses at the extreme fibre will reach the limit of proportionality and soon after that the yield point of the material f_y (fig. 18(A)). Further increase in load and bending moment can no longer produce any increase in the maximum bending stresses in the extreme fibres. These will yield at constant stress so that the increase in bending moment has to be absorbed by material closer to the neutral axis which in turn will reach the yield point stress of the material as is shown in fig. 18(B). Two zones of yielding will develop which will spread toward the neutral axis and along the beam as the load is increased. Eventually the state of fig. 18(C) will be attained when the material has reached yield point stress throughout the cross section. No further increase in stress in this cross section is possible until the material begins to work harden. Before this work hardening can set in, the deformations would, however, have grown so large that the beam would have become useless. Thus, the condition shown in fig. 18(C) must be assumed to characterize the maximum load carrying capacity of the beam.

The distribution of bending stress of fig. 18(C) in fact represents a limiting condition and the bending moment represented by this stress distribution is called the full plastic moment of the cross section. When this full plastic moment is reached the two parts of the beam on either side of this fully plastic cross section will continue to rotate at constant load. This condition means, however, that the beam is no longer a structure but a mechanism as shown in fig. 17(B). The cross section which has become fully plastic has the same effect as the insertion of a friction hinge in the beam. The full plastic moment for a rectangular cross section of depth d and width b is given by $M_p = \frac{bd^2}{4} f_y$, where f_y is the yield point stress of the material.

If, instead of a freely supported beam as in fig. 17(A) a beam is considered whose ends are encastered (fig. 19(A)), that is, prevented from rotation, plastic hinges will form not only at a section

FIG. 18.—BENDING STRESS DISTRIBUTION IN CROSS SECTION OF BEAM SHOWN IN FIG. 17. (A) EXTREME FIBRE STRESS AT YIELD POINT; (B) YIELD POINT STRESS REACHED IN MOST OF CROSS SECTION; (C) YIELDING HAS TAKEN PLACE THROUGHOUT. THE BENDING MOMENT HAS REACHED THE FULL PLASTIC MOMENT

within the span but at the encastered ends. It is only when three hinges form that the beam becomes a mechanism (fig. 19(B)), and its full carrying capacity is attained.

Such a structure in which more than one hinge must be formed before it is converted into a mechanism, is called a redundant structure. The portal frame in fig. 20 under vertical and horizontal load will not, in general, become a mechanism until four such plastic hinges are formed.

The carrying capacity of the encastered beam of fig. 19 is twice as large as that of the simply supported beam of fig. 17(A) although the two beams are otherwise identical. This condition is due to the two extra hinges which can be formed in the encastered beam before collapse takes place. On the basis of elastic theory and permissible stresses the encastered beam would only be considered 1.5 times as strong. This example shows that plastic theory permits the more effective exploitation of the reserves of carrying capacity which ductile redundant structures are shown to possess in comparison with statically determinate structures.

The preceding considerations have left out of account the fact that a beam subjected to bending is generally subjected to shear stresses at the same time. These do not, however, exercise a pronounced influence on carrying capacity in the case considered and can usually be neglected. The presence of other stresses in addition to one normal stress cannot, however, always be neglected and a general problem arises to which reference has already been made in a different context. This is the problem: Supposing that yielding occurs in uniaxial tension at a stress f_y , what is the individual value of the stresses X_1, Y_2, Z_3 , the three principal stresses characterizing a general triaxial state of stress, when yielding is due not

FIG. 19.—(A) BEAM WITH ENCASTERED ENDS WITH UNIFORMLY DISTRIBUTED LOAD; (B) FORMATION OF THREE PLASTIC HINGES CONVERTS BEAM INTO A MECHANISM

to simple tension but to this triaxial state of stress?

Hypotheses of Yielding or Elastic Breakdown.—*Principal Stress Hypothesis.*—The simplest hypothesis would be to postulate that if X_1 is the largest of the three principal stresses so that $X_1 > Y_2 > Z_3$ the stresses Y_2 and Z_3 have no influence on yielding. This hypothesis is not borne out by experiment. While it is impossible in the laboratory to realize and measure uniform triaxial states of stress, biaxial states of stress can be realized either by the twisting of thin tubes in which the two principal stresses are equal but of opposite sign, X_1 tension, $Y_2 = -X_1$ compression and $Z_3 = 0$, or by subjecting thin tubes to internal pressure in which case X_1 , the largest stress, is the circumferential or hoop stress, and Y_2 , the longitudinal stress, occurs in the direction of the axis and is equal to half the circumferential stress $Y_2 = \frac{1}{2}X_1$.

It was found experimentally by W. Lode that thin tubes subjected to twisting yield when $X_1 = -Y_2 = 0.6 f_y$. Thus yielding takes place under these conditions when the stresses are equal to only 60% of the yield point stress in simple tension, from which it must be concluded that the principal stress hypothesis is untenable.

Principal Strain Hypothesis.—This hypothesis postulates that

FIG. 20.—RIGID PORTAL FRAME

the maximum principal strain is constant at the onset of yield irrespective of the state of stress. If we postulate a somewhat simplified stress-strain diagram for the material which is generally used in plasticity and in which the region of proportionality (straight line relation) OA (fig. 21) is assumed to be valid up to the yield point of the material, followed by an unlimited yield range AB with no work hardening, we obtain the maximum strain at yield $\epsilon_y = fy$. For the tube subjected to twisting we obtain

$$\epsilon_1 = \frac{1}{E} [X_1 - \mu(Y_2 + Z_2)] = \frac{1}{E} [X_1 - \mu(-X_1 + 0)]$$

$$\epsilon_1 = \frac{X_1}{E} (1 + \mu)$$

and since μ for steel is approximately 0.28 we obtain

$$\epsilon_1 = \epsilon_y = \frac{X_1}{E} \times 1.28 = \frac{fy}{E}$$

and hence $X_1 = \frac{fy}{1.28} = 0.78 fy$

Experiment, however, demands $X_1 = 0.6 fy$ so that this hypothesis cannot be maintained.

Maximum Shear Stress Hypothesis.—According to this hypothesis yielding depends on half the difference between the largest and the smallest of the two principal stresses which equals the largest value of shear stress. Yielding is, therefore, assumed to take place when the largest shear stress assumes the value of the shear in uniaxial tension at yield. In uniaxial tension the largest shear stress is one-half the applied tensile stress, hence at yield when $X_1 = fy$ the largest shear stress is $0.5 fy$. For the tube subjected to twisting, the largest shear stress = $\frac{X_1 - Y_2}{2} = \frac{X_1 + X_1}{2}$

and this must be equal to $0.5 fy$ hence $X_1 = 0.5 fy$. Experiment demands $X_1 = 0.6 fy$ and this is therefore a good approximation.

Shear Strain Energy Hypothesis.—This, also known as the Mises, Huber, Hencky hypothesis, postulates that the capacity of the material to absorb shear strain energy without yielding is limited to a constant value and that this value is independent of the state of stress.

Earlier we found the shear strain energy U_2 to be

$$\frac{1+\mu}{6E} [(X_1 - Y_2)^2 + (Y_2 - Z_2)^2 + (Z_2 - X_1)^2] + \frac{1}{2G} (X_1^2 + X_2^2 + Y_2^2)$$

and written in principal stresses this expression becomes

$$U_2 = \frac{1+\mu}{6E} [(X_1 - Y_2)^2 + (Y_2 - Z_2)^2 + (Z_2 - X_1)^2]$$

For uniaxial tension at yield $X_1 = fy$ $Y_2 = Z_2 = 0$ and

$$U_2 = \frac{1+\mu}{6E} (X_1^2 + X_1^2) = \frac{2(1+\mu)}{6E} fy^2$$

For the tube under torsion $X_1 = -Y_2$, $Z_2 = 0$ and

$$U_2 = \frac{1+\mu}{6E} [(X_1 + X_1)^2 + X_1^2 + X_1^2] = \frac{6(1+\mu)}{6E} X_1^2$$

hence $X_1^2 = \frac{1}{3} fy^2$ and $X_1 = \frac{1}{\sqrt{3}} fy = 0.58 fy$

Experiment demands $X_1 = 0.6 fy$ and it is seen that this hypothesis represents experimental results more accurately than any of the other hypotheses. It is now generally accepted as the hypothesis for elastic breakdown or yielding.

Since for hydrostatic states of stress for which $X_1 = Y_2 = Z_2$ the value of U_2 vanishes, yielding cannot occur, however large the magnitude of the principal stresses. This is borne out by experience since metals will tolerate enormous hydrostatic pressures without yielding.

Triaxial isotropic tension with all three principal stresses equal would also make yielding and plastic deformation impossible however large the principal stresses are. It would then have to be assumed that fracture supervenes even in ductile materials without being preceded by plastic deformation. Some authorities in the past have attributed the occurrence of brittle fracture in normally ductile materials to the existence of such states of isotropic triaxial tension. There are, however, objections to this interpretation.

Instability and Buckling.—If a ball is considered resting within a hemispherical shell it is in stable equilibrium because after any small displacement from its position it will return to its original equilibrium position. The potential energy of the ball is a minimum and this is characteristic for stable equilibrium. The potential energy of a ball resting on the outside of a hemispherical shell is a maximum and hence after a small displacement it cannot return to its equilibrium position which is unstable. The ball will roll off altogether after a small displacement from this equilibrium position and may assume another stable equilibrium position by the side of the hemispherical shell.

A somewhat similar situation arises in many cases of stressed solids. The internal stresses with the associated deformation must be in equilibrium with the external forces in the same way as the weight of the ball, when at rest, is in equilibrium with the pressure exerted on it by the supporting shell. But in the same way as the equilibrium of the ball can be either stable or unstable, that of the stressed solid can be stable or unstable. If the equilibrium is unstable a small deformation may cause the pattern of equilibrium to change radically to a stable form, but this change may be associated with such large deformations that it must be considered as failure. Because these deformations frequently appear as buckles this phenomenon of instability is known to the engineer as "buckling." A thin cylindrical shell after buckling under compression is shown in fig. 22.

The commonest form of buckling is that of a column or pillar supporting a load. For loads not exceeding a certain value the axis of the column remains straight, but as the load increases the stored

FIG. 21.—SCHEMATIC STRESS-STRAIN DIAGRAM. AB YIELD RANGE

DEPARTMENT OF ENGINEERING, UNIVERSITY OF CAMBRIDGE

FIG. 22.—THIN CYLINDRICAL SHELL BUCKLED BY AXIAL COMPRESSION

strain energy increases and may become a maximum. This means that when the load reaches a certain limiting value, the buckling load, another equilibrium position of smaller potential energy becomes possible but no longer with the column axis straight, but curved. At the moment of buckling, each point along the axis will move laterally—as if to shed and evade the load—and the column will no longer be straight but curved and may collapse altogether if another equilibrium position cannot be found for only small displacements.

Every structure or part of a structure in which there are compressive stresses is potentially liable to buckle, although the danger is real only for relatively slender or thin-walled structural members. Buckling is not necessarily always destructive as every airplane passenger is able to observe by looking out at the somewhat crinkly skin of the wing when the plane is air-borne, whereas this skin before buckling, while the airplane was on the ground, was perfectly smooth.

Buckling as an equilibrium problem is not associated with the compressive strength of the material as discussed in the section on compression tests although certain mechanical properties such as Young's modulus and the yield point of the material may enter into the problem. Largely, however, buckling is a function of form—a long straight column will collapse under a much smaller load than a short column of the same material and cross section, though the stresses in the two members would be the same under the same load. Buckling may take place entirely within the elastic region of the material and for such cases solutions may be found by applying the theory of elasticity. It will always be advisable, though, to check such solutions by experiment. Whereas the theory of elasticity gives results in the case of columns in good agreement with experiment, at least for columns of such slender proportions that they will buckle within the elastic region of the material, in other cases this is not so. In the case of the axially compressed thin-walled metal cylinder with a large ratio of diameter to wall thickness, such as that illustrated in fig. 22, the theory of elasticity gives solutions for the buckling load which may be three to four times as large as those found by experiment.

The mathematical solution of all but the simplest buckling problems poses formidable difficulties even if it is fully within the elastic region. These difficulties are enormously increased for buckling problems involving partly plastic deformation, and progress in this field is as yet extremely limited.

Thus, theoretically complete solutions, confirmed by experiment, are not available for many cases of engineering application. Even relatively ancient and common problems, such as the buckling of webs in plate girders and the necessary stiffening, are still the subject of controversy and research, so that the engineer frequently has to rely on the results of past experience and on *ad hoc* tests to prevent failure of his structures from instability.

Fatigue.—Reference to failure by fatigue has already been made under *Fatigue Tests*. The problem must now be considered in its broader aspects. Only a few engineering structures or components are loaded in such a way that the load once applied remains constant for the whole of the life of the structure. In most cases there will be variation of stress, and since fatigue failure is a phenomenon resulting from such variation, almost every engineering component is exposed to the risk of failure from fatigue. Variation of stress may result even if there is no variation in load. The axle of a railway car, even if the axle load remains constant all the time, is nevertheless subject to fatigue. It acts as a beam so that there are always tension stresses on the underside of the axle and compression stresses on top. Since the axle is not stationary but revolves, the material in tension at one moment will be subjected to compression the next moment when the axle has completed half a revolution, and after a further half revolution will be subjected to tension again.

In this case the alternations of stress are sinusoidal and of constant amplitude. This is by no means the case generally. The wings of an aircraft during flight are subjected to many, though quite irregular, alterations of loading depending on the velocity of gusts so that the stress cycles in the wing will be distributed at random between a maximum and a minimum stress. Such random

loading complicates the fatigue problem enormously since fatigue data, insofar as they are available, have been obtained for cyclic loading of constant amplitude.

The number of loading cycles endured during the lifetime of a structure may also vary enormously from one type of structure to another. One hundred million loading and unloading cycles may have to be endured in the lifetime of a bridge outside the main line station of a capital city, whereas a similar bridge in some remote part of the country may only be loaded a few times every day. It is estimated that a railway bridge may have to endure between 1,000,000 and 100,000,000 cycles of loading, the axle of a railway car 400,000,000 cycles, and the shaft of a steam turbine 15,000,000,000 cycles of loading. Each blade of a modern aircraft gas turbine may have to endure 60,000,000,000 stress cycles in 500 flying hours. Even if testing machines were available for applying 200,000 cycles of loading per minute, a test on such a turbine blade would still take about a month. At the other extreme, even a few thousand cycles may be sufficient to produce fatigue as the investigations into the failure of the pressure cabin of a famous airliner have shown.

The frequent occurrence of service failure from fatigue is entirely due to the completely inadequate design procedures. In them the stresses in the structure are calculated by some approximate method based on the theory of elasticity and are then limited to some value near the proportional limit of the material or, which comes much to the same thing, to some fraction of the material's fatigue strength determined in tests with small metal specimens. Such procedures leave out of account many effects of which only a few important ones can be considered here.

Notch Sensitivity and Size Effect.—Under conditions of fatigue, as has been explained, the material does not deform plastically in bulk as under static loading. Plastic deformation is definitely associated with fatigue but it occurs on a microscopic scale so that it may be highly localized, concentrated as it were at certain points, where a fatigue crack will then start. A micro-section through a piece of mild steel containing a fatigue crack is shown in fig. 23. These points where the microscopic plastic deformation is concentrated will naturally be those where the stresses are highest, that is, at points of stress concentration. Fatigue failures almost without exception will start from points of stress concentration produced by discontinuities in form, either necessarily introduced in design or manufacture such as riveted, bolted or welded joints, shoulders in shafts, oil holes and keyways, or accidentally introduced in manufacture such as tool marks, grinding scratches, accidental indentations, electric arcing marks, small defects such as blowholes in castings and similar minor damage.

Since the fatigue crack starts at a point, it will be the magnitude of stress at this single point which decides whether in fact the part survives in service or fails.

This might appear, at first sight, to simplify the problem, since all the designer has to do is to ensure that the stress at this critical point does not exceed the endurance limit of the material. One of the difficulties is to find the "point," although experience frequently helps greatly in pinpointing the discontinuity most likely to produce the critical stress concentration.

The second difficulty arises in determining the exact value of the stress before the part is made. Mathematical analysis will give solutions in some cases but fails in others. There was, for instance, in the early 1960s, no method of evaluating accurately the stress cycle experienced by the material at the root of gear teeth when the gears are running, particularly if the gears are of more complex form than straight spur gears. In many other common engineering components the situation was similar, though in some cases the value of the peak stress could be determined by one or other of the methods of experimental stress analysis.

Finally, even if the stress value is accurately known, it is not sufficient for this value to be simply limited to the fatigue strength of the material. For one thing, as has already been pointed out, fatigue strength is not a mechanical property depending only on the material. Fatigue tests carried out with identical specimens of rectangular cross section, for instance, will give different values for the "fatigue strength of the material" depending on whether

the specimens are tested by applying axial tension, bending about the minor axis of inertia (specimen bent on the flat) or about the major axis (specimen bent on edge). A different result will be obtained for specimens with sharp edges. The surface finish of the specimen whether as rolled, machined, ground or polished will also profoundly influence the result, so that it is really impossible to define the fatigue strength of the material.

Secondly, the reduction in fatigue strength is not necessarily proportional to the value of the stress concentration factor as defined earlier. If, for instance, the fatigue strength of two components is determined experimentally, the two being identical with the exception of some minor detail which produces the stress concentration—such as a variation in the radius of the transition between pin and web of otherwise identical crankshafts—it is found that the reduction in fatigue strength is not proportional to the values of these stress concentrations. Moreover, if the fatigue strength of two crankshafts entirely similar in form but of different size is compared, the fatigue strength of the larger shaft will be smaller than that of the smaller shaft despite the fact that the stress concentrations for both shafts are the same.

This phenomenon of increasing effectiveness of stress concentration with size is known as the size effect in fatigue.

More "highly cultivated" materials, where high values of tensile strength are produced by careful alloying and heat treatment, suffer relatively greater losses in fatigue strength through the presence of a stress concentration than some more ordinary materials such as gray cast iron. This difference between different materials to suffer relatively greater or smaller reductions in fatigue strength in consequence of stress concentrations produced by notches or other geometric discontinuities is spoken of as the differing "notch sensitivity" of different materials.

There is, however, one important overriding consideration which to some extent at least simplifies matters. Provided the magnitude of the worst stress concentration can be accurately evaluated, the reduction in fatigue strength will never be greater than that which could be expected by dividing the fatigue strength of the material, obtained of course in an appropriate test with a test piece of similar characteristics and subjected to types of stressing similar to that of the component, by the full value of the elastic stress concentration factor. That the value of fatigue strength used must be chosen with great care is perhaps evident when it is considered that a steel rail of 50 tons per square inch tensile strength when tested in the form of machined specimens in bending will give a fatigue strength of perhaps 30 tons per square inch, whereas the actual rail even without stress concentrations will give scarcely more than 24 tons per square inch in bending; when stress concentrations are introduced by the circular holes of the fishplated joint, no more than 8 tons per square inch can be expected.

Cumulative Damage.—Many engineering structures and components are not subjected to stress variations of constant amplitude. The stresses experienced in a ship during a voyage will largely depend on the weather experienced, and similar considerations will apply to aircraft. Experimental means were at the disposal of the engineer in the late 1950s to obtain extensive records of the stress variations for such cases. In the 1950s testing machines were developed capable of applying "program loading"; that is, loading of an amplitude which can be varied in a regular manner during the fatigue test to approximate more closely to conditions in service where a few cycles of high stress amplitude may be followed by thousands or millions of cycles of low amplitude, in

DEPARTMENT OF ENGINEERING, UNIVERSITY OF CAMBRIDGE

FIG. 23.—MICROSECTION THROUGH STEEL CONTAINING FATIGUE CRACK

contrast to the constant amplitude of stress applied in the conventional fatigue test. The problem of predicting the life of a part subjected in service to stress cycles of variable amplitude, from experimental data obtained with the aid of constant amplitude machines, is known as the cumulative damage problem.

Various methods for assessing cumulative damage have been proposed, based on statistical reasoning, but the problem is still unsolved and will only be solved when the fundamental mechanism of fatigue is better understood. The many theories proposed explained fatigue with the aid of some conceptual model behaving in accordance with the known laws governing the deformation of metal crystals, but none of them had found general acceptance.

Statistical Aspects.—Until the late 1950s it was assumed that ferrous metals have a limiting stress—the endurance limit below which fatigue failure cannot occur—and that this stress can only differ by an insignificant amount from that which still produces failure at 10,000,000 cycles. This would mean that if a part does not fail in 10,000,000 cycles it will not fail at all. Service failures after much longer endurance, thousands of millions of cycles, are, however, not unknown and perhaps it would be more correct to say that if a part does not fail after 10,000,000 cycles it is unlikely to fail at all. This expression "unlikely" introduces a probability aspect into the fatigue phenomenon for which there is increasing experimental support.

For one thing, the S-N diagram discussed earlier is never obtained as a smooth curve passing exactly through the experimental points. In fact, if instead of testing only one specimen at a given stress level, several are tested, each of them will give a different endurance, that is, a different value for N , so that the test results will exhibit more or less scatter. The different values will be distributed in accordance with some frequency distribution. It would appear to follow from this that the life of a specimen subjected to a certain amplitude of cyclic stress cannot be predicted accurately. All that can be said—and even this only if there are sufficient experimental data—is that any given specimen may have a certain definite chance to survive a given number of cycles at a certain stress value. Instead of plotting S-N diagrams one would plot S-N-P diagrams consisting of several lines similar to the conventional S-N diagram, but each of them associated with a certain probability of survival " P ." If the S-N diagram were drawn in such a way that, if for a given value S , n specimens have been tested, and the S-N diagram would be made to pass through a point corresponding to N cycles, so that $n/2$ results lie to the right of it and $n/2$ to the left, it could be concluded that the chance of a specimen surviving to the endurance of N cycles at the given stress is $\frac{1}{2}$. The S-N diagram drawn through these points for different values of S would be the S-N diagram for 50% probability, and other S-N diagrams for different probabilities of survival could be obtained in a similar manner.

The lives or endurance of fatigue specimens could be considered to be distributed in accordance with some mathematical frequency distribution in much the same way as the ages of man at death.

The determination of this frequency distribution is one of the cardinal problems for research workers in this field. That fatigue is in fact a statistical phenomenon is becoming widely realized, but engineers are reluctant to accept the inescapable consequence, that however "safe" an engineering part is designed it may nevertheless fail from fatigue. Where millions of identical parts are used in mass-produced machinery such as automobiles, a few of this large number will inevitably fail.

If the frequency distribution for fatigue failure were known, the engineer might on this basis deliberately select a priori the number of failures he is willing to tolerate as a percentage of total production, instead of hoping that it will be tolerably small.

Full-Scale Tests.—It will be clear that no fatigue problem can be solved satisfactorily without fairly extensive experimental data. In the complete absence of fundamental principles upon which to build a reliable theory, engineers are driven increasingly to the full-scale prototype fatigue test of which perhaps the most notable development has been the testing to destruction of complete pressure cabins of large airliners under repeated internal pressurization. Full-scale tests of this and similar types, of course,

can no longer be carried out in testing machines. They require an extensive, complex and costly plant, but at the state of knowledge in the mid-1960s they cannot, unfortunately, be dispensed with.

Creep.—This subject until the early 1950s was of almost purely academic interest. With the rapid increase in the working temperatures of steam-power stations, however, and in particular with the development of the gas turbine and the modern jet engine, the subject has assumed tremendous importance.

If a tensile test, as discussed earlier, is interrupted at a point C (fig. 12), say, on the load extension diagram and the load is maintained at the value represented by C, the specimen will continue to deform at constant load for a long time. This type of plastic deformation which may eventually end in fracture is called creep. On the application of the load the time rate of deformation will at first decrease (primary creep), then remain fairly constant (secondary creep) and then increase just prior to fracture (tertiary creep). The whole process may take place within a few hours or within hundreds of thousands of hours depending on the applied stress, the material and the temperature.

The fabrication of metals by forging, rolling or extrusion is generally carried out at higher temperatures because the resistance of the material against deformation decreases with increasing temperature, but this also means that for a given applied stress the total creep in a given time will increase with increasing temperature and at a given temperature with increasing stress.

Quite apart from the need to avoid failures in steam plant and gas turbines, the deformations which can be permitted to take place within the required service life are necessarily limited to small amounts. If the blades of a gas turbine were permitted to elongate appreciably by creep under the influence of the centrifugal forces, they would soon begin to rub on the casing. The temperatures at which ordinary engineering steels can be used without excessive creep are modest and special steels alloyed with molybdenum, nickel, chromium and vanadium must be used for the high temperatures of a modern steam plant. For the temperatures produced in gas turbines even these steels are not satisfactory, and alloys primarily consisting of nickel and chromium, the "Nimonic" alloys, were developed for jet engines.

Further increases in jet engine efficiency could be obtained if higher engine compression could be used at present operating temperatures or higher operating temperatures for present engine compressions. In both cases higher creep resistance than that offered by present materials is required. One of the materials used was "Nimonic 80." It would suffer an extension of 0.5% in 10,000 hours at a temperature of 750° C. under an applied stress of four tons per square inch. This type of information essential to the designer is obtained in creep tests. Specimens are tested in tension in specially designed machines which permit the application of loads of varying magnitude within a furnace kept at constant temperature. Apparatus for measuring the creep under load with time must also be provided.

One difficulty in creep testing arises from the fact that the cross-sectional area of the specimen diminishes as creep proceeds and if the load is kept constant the stress applied to the specimen will gradually increase during the test. Most creep tests are nevertheless carried out at constant load and the error is not large if the diminution of cross section remains small. Some ingenious devices, however, have been developed for keeping the stress constant rather than the load. Creep tests are carried out in several different ways and according to the method adopted different types of information will be obtained.

In the "creep rupture test," also known as "time to rupture test," the specimen is loaded at constant load and the time to rupture at constant temperature is observed. By testing a number of specimens at the same temperature but at different stresses and plotting stress against time to rupture, curves are obtained which in appearance are not unlike the S-N diagrams obtained in fatigue tests but with time taking the place of numbers of cycles. While such tests will give no information on the amount of deformation, they will give a good indication of the stress values which might be used at different temperatures without causing rupture within a given period of time. In another type of test, the Rohn test, the

temperature is determined at which creep will cease under given stress.

Since the amount of deformation suffered by the material at a given stress and temperature within a given time is of great importance in many practical cases, it has been found necessary to perform creep tests of 10,000 hours' duration at different stresses and temperatures. To obtain complete information of this type within a reasonable time requires batteries of creep-testing machines. Even then it is necessary for the engineer to extrapolate from say 10,000 hours to 100,000 hours which might represent the required service life of a steam pipe. In this light it is perhaps understandable that such problems as the effect of triaxial states of stress, or the effect of nonuniform stress distribution, or the effect of stress concentrations on creep behaviour, has not as yet been investigated to any appreciable extent. It is clear, however, that failure by creep need be considered only for those engineering components which must operate at high temperatures and where, as in steam plants, cooling is impossible. In gas turbines internally cooled blades have been adopted. These enable greater operating temperatures to be used than would otherwise be possible with existing materials. Creep and fatigue frequently arise together and present a problem which is not yet resolved.

Corrosion.—Corrosion is certainly one of the agents responsible for many failures though its connection with strength of materials may seem remote. There is the obvious weakening in consequence of the profound change in the strength properties of metals when they are converted into chemical compounds by cor-

BRITISH WELDING RESEARCH ASSOCIATION

FIG. 24.—MICROSECTION THROUGH STEEL CONTAINING INTERGRANULAR STRESS CORROSION CRACK

rosion, but there are at least two other phenomena in which corrosion plays a more immediate part in the destruction of the strength of a metal.

Corrosion fatigue is one of them. The fatigue strength of all but passivated metals, that is to say, those not liable to corrode in certain mediums, will be greatly reduced by the presence of a corrosive medium. Even that of passivated metals may be reduced if the passivity depends on a surface film which cracks under the influence of fatigue loading conditions and cannot be repaired rapidly enough.

Thus stainless steel, which does not corrode in water, has its endurance limit reduced from 23 tons per square inch to 16 tons per square inch when tested in water. It is clear from this that the most elaborate design procedures may be useless if the designer leaves out of account the possible presence of a corrosive medium, and there is no evidence that paints, which may prevent general corrosion, would effectively prevent this reduction in fatigue strength.

Stress corrosion is another way in which a corrosive agent can

rapidly destroy the resistance of a material to stress. Whereas, in the absence of stress, a corrosive medium may produce only slow general surface corrosion, in the presence of stress the attack may become highly localized and accelerated. In this case deep cracks will develop rapidly, such as that shown in fig. 24, generally along the grain boundaries of the metal, where, in the absence of the corrosive medium, stress by itself would not produce such cracking. Stress corrosion cracking may occur in riveted boilers in consequence of alkali concentrations building up in riveted seams from alkali dissolved in boiler-water treatment. This phenomenon is also known as caustic cracking. An atmosphere containing traces of ammonia may produce cracking in brass articles especially when these have been produced by cold-working processes. This is known as season cracking. Stainless steel and aluminum alloys also are liable to suffer such destruction in the presence of certain chemicals.

Brittle Fracture.—This term in its original meaning denoted fracture of a brittle material such as glass which occurs suddenly at a certain stress without being preceded by any plastic deformation. However, the term was used increasingly to denote not the fracture of a brittle material but that of a ductile material, in particular carbon steel, in an unusual and to all appearances perfectly brittle manner. There is in fact a small amount of plastic deformation present, though this is only revealed by accurate measurement.

Such brittle fractures have occurred in large structures such as bridges, ships and oil storage tanks. All these failures have certain common features: (1) they have occurred mainly in welded structures though a few riveted structures have been affected; (2) in only a few cases was the steel found to be below accepted high standards of quality; (3) the fracture generally occurred suddenly without warning and progressed along its path with great speed; (4) in most cases the ambient temperature was relatively low; (5) the fracture generally originated from one or several geometric discontinuities which produced stress concentration; (6) all the fractures were produced at ordinary working stresses below the proportional limit of the material; (7) the static tensile strength and ductility of the material when tested at the casualty temperature were satisfactory; in particular the material exhibited large ductility.

Although isotropic triaxial states of tensile stress might permit a ductile material to fail in a brittle manner in accordance with the shear strain energy hypothesis for plastic deformation discussed earlier, this simple explanation is not satisfactory for several reasons. For one thing, it is difficult to see why such triaxial states of stress, even if there were grounds to suspect that they might exist in such extensive areas of structures, should be tolerated by the structure at one temperature and not at a somewhat lower temperature.

Although the problem of brittle fracture of ductile steel was far from being solved in the mid-1960s, it began to be better understood when it was shown by C. F. Tipper that a tensile test piece with a notch could break either in a perfectly ductile or in a brittle manner depending entirely on the testing temperature. The fractures experienced were then seen to be due primarily to a change in a property of steel termed notch toughness in consequence of decreasing temperature.

Why exactly this change in property takes place was not clear to researchers, but it was known that the relation between the notch toughness of a steel and the temperature is strongly influenced by the steelmaking process, the chemical composition of the steel, the temperature at which the steel is rolled and the thickness in which it is produced. In general, the notch toughness decreases with increasing thickness of material, and plates one inch thick of material produced to current specifications would generally show signs of becoming notch brittle at ordinary room temperature. This change in notch toughness would not become evident from test results obtained with the standard tensile test commonly used for the acceptance and quality control of ordinary structural steel for such as is used for ships, bridges, buildings, storage and pressure vessels.

Since the standard tensile test gives no indication that the ma-

terial may be notch brittle at the temperature at which it is to be used, it is important that a test be devised which would permit the selection of materials suitable for service at different ranges of low temperature. For economic reasons the test should be not too severe, but for reasons of safety it must be sufficiently discriminating to exclude material which might become dangerous, since if fracture occurs it does so at quite modest stress levels, not due to overload. Such a test must fix for each steel a narrow temperature range above which a structure made from the steel could not fail by brittle fracture, and below which it would be likely to fail. A large number of different tests have been proposed but none has so far been generally accepted as giving the perfect correlation with expected service behaviour. Some tests, such as the notch tensile test proposed by Tipper, are certainly safe but are claimed to be too severe. Other tests such as the Charpy V-notch impact test are considered not to be severe enough.

There are certain indications that it is in fact inherent in the nature of the problem that such an ideal test cannot be devised. For one thing, there is a fundamental difference in the failure of the structure and that of a test piece. Structures have definitely been known to fail at stresses well below the yield point stress of the material, whereas none of the many test pieces proposed can be broken at stresses below the yield.

It appears as if in the structure not only the notch ductility of the material is reduced by the decrease in temperature, but its brittle strength as well, and this is never found in the test piece.

This apparent drop in strength, however, is better understood since A. A. Wells succeeded in reproducing at low stresses in the laboratory such fast brittle through fractures in large welded test pieces.

Two stages in the fracture have to be distinguished: initiation and propagation. Initiation requires the stress at the bottom of the notch to be raised to yield point magnitude. The plastic deformation produced in welding by the severely localized heating will, however, do this, so that an external load producing yield point stress is not required. The second stage of fracture, propagation, is an instability effect.

A. A. Griffith proposed a criterion for the propagation of a fast fracture starting from an internal notch in a brittle solid such as glass. As the internal notch or crack extends, new surfaces are created for which surface energy is required. This cannot be supplied by the external loads since the fracture propagates so rapidly that the external loads cannot move and cannot, therefore, do any work. The energy can, however, be derived from the interior of the solid, since, as the fracture propagates, increasingly large portions of the material become stress free and strain energy is released. If the strain energy release rate exceeds the rate at which energy is absorbed in the form of surface energy in the newly created surfaces, the process is clearly unstable and must proceed at an accelerated rate.

G. Irwin, by interpreting "surface energy" in such a way as to include the energy absorbed in the plastic deformation of two narrow zones at each side of the crack in a steel plate, showed that the same instability effect could explain the rapid propagation of fractures in large structures. The level of the energy to be liberated in crack propagation depends, of course, on the material and the general stress level. High stresses are necessary to propagate small cracks, but the general stress level necessary for propagation rapidly decreases as the length of the fracture increases. High stresses are always present in the form of residual stresses in the immediate vicinity of welds in welded structures, and Wells's experiments have shown that the strain energy from the relief of these residual stresses is sufficient to supply the high strain energy release rate required in the early stages of the extension of a small crack from a weld at low average applied stresses.

V. METAL PHYSICS

The vast number of questions arising in the problem of the failure of metals by plastic deformation, creep, fatigue and brittle fracture which cannot be satisfactorily explained with the aid of the fundamental concepts of the theory of elasticity have given rise to innumerable and diverse investigations, both theoretical and

experimental, which have only one feature in common: that they endeavour to take account of the structure of metals instead of operating with the abstract structureless elastic space of the theory of elasticity. By the 1960s investigations of this type were generally considered to fall within the province of metal physics, though metal physics is concerned with many problems other than strength.

Structure of Metals.—Metals are composed of aggregates of small crystals as can be seen from the microsections in fig. 23 and 24. Whereas crystals grown in a solution have regular plane boundaries, the crystals in metals are of quite irregular shape because on solidification of a metal from the liquid state, many crystals grow simultaneously and then meet along irregular grain boundaries. This original cast structure generally is profoundly modified by later working and heat-treatment processes.

A solid is a crystal when the atoms are arranged in a regular pattern which is repeated throughout the solid. The atoms of iron, for instance, arrange themselves in such a manner that eight of them occupy positions at the corners of a cube and the ninth places itself in the centre of the cube. This arrangement of the crystal is called a body-centred cubic lattice. The existence of such structures can be verified experimentally by the methods of X-ray crystallography which are based on the diffraction phenomenon. These methods also permit the determination of the distance between the atoms, the so-called lattice constant, which for the body-centred cubic lattice of iron is 2.8 Å or 2.8×10^{-8} cm.

Elastic Deformation.—This can be shown to produce changes in the distance between atoms, and this fact has been used for purposes of experimental stress analysis. The change in the lattice constant as measured by X-ray diffraction can be related to the applied stress so that X-ray diffraction can be used for stress analysis though the method has severe limitations.

Plastic Deformation; Slip.—This has been studied extensively with the aid of single metal crystals which can be produced by straining and heat treatment up to several inches in length. Such single metal crystals do not, of course, exhibit the regular arrangement of plane boundaries one generally associates with a single crystal, but unlike polycrystalline materials the orientation of the atomic lattice planes is the same throughout the crystal, the essential criterion for the crystal being "single."

It is found that plastic deformation proceeds by individual layers of atoms in lattice planes of definite orientation with regard to the faces of the cube sliding over each other like a pack of cards. This can be seen under the microscope in the form of so-called slip lines which are edges of blocks of lattice planes breaking the surface after slip.

Resistance to Slip.—From the forces of attraction between the atoms the resistance against this deformation can be calculated, and is found to be about 1,000 times as large as that actually measured in experiments. Actually, single crystals generally are relatively soft, their resistance against plastic deformation is much less than that of the same material composed of many tiny crystals. This lessened resistance is understandable since the irregularly arranged atoms in the grain boundaries may, to some extent, delay the movement of the glide planes.

Dislocations.—The insertion of a few foreign atoms into the lattice, such as carbon in iron, will increase the resistance against deformation. Steels are made creep resistant by the addition of quite small quantities of foreign atoms. On the other hand, the postulation of irregularities in the lattice which can be produced by the insertion of additional atoms into one plane, or by assuming vacant lattice sites, can be used to explain the small deformation resistance of actual metal crystals. These irregularities have been termed dislocations and a whole theory of strength, the dislocation theory, has developed which endeavours to explain many of the phenomena revealed by observation and experiment and which in fact is successful in explaining the small strength of simple crystals in relation to the theoretical strength and many diverse effects observed in plastic deformation.

Cleavage.—Crystals can, however, not only be plastically deformed, but they can be split by cleavage along certain crystallographic planes, the so-called cleavage planes well known from

the observation of the exfoliation of mica. Crystals cleave frequently during plastic deformation. A fracture which consists primarily of cleavages of undeformed crystals would be a brittle fracture, and whether brittle or ductile fracture occurs in a piece of metal may depend on the stress components acting in the glide planes and in the cleavage planes, and the relative resistance against slip and cleavage. The resistance against slip is certainly known to increase with decreasing temperature, and if the cleavage strength remained constant it would be natural to expect an increasing number of crystals in a polycrystalline material to fail from cleavage as the temperature decreases. Thus, with decreasing temperature fracture would tend to become increasingly brittle.

Metal Physics and Engineering.—Despite the great contribution these physical considerations have made to our understanding of deformation and fracture phenomena, we are as yet far from having established a unique set of simple fundamental principles which would permit satisfactory explanation for the observed phenomena. The situation in the mid-1960s was this: that principles which permit one group of phenomena to be explained satisfactorily are in direct contradiction with other phenomena. The whole subject was still so much in a state of flux that it would be unwise in this article to do more than indicate some elementary facts which are firmly established.

While metal physical theories of strength have made notable contributions to our understanding of many of our strength problems, they have not developed in a direction in which the engineer can make use of them directly in his problem of design for strength. This situation is, to some extent, a consequence of the fact that physical theories are postulated for pure metals whereas engineers use metals which are anything but pure. Steel contains, as well as iron, carbon in solid solution and iron carbides in the form of a second phase. Brass consists of a mixture of copper and zinc crystals, stainless steel contains impurities to the extent of 18% chromium and 8% nickel, and all engineering metals contain gases such as hydrogen, oxygen and nitrogen together with other metallic and nonmetallic impurities. These trace elements in metals are nevertheless known to have such a profound influence on mechanical behaviour that their presence or absence is often the only criterion determining whether or not a metal can be safely used for a given purpose. In view of these and other facts one is reluctant to advise engineers to look to metal physics for the ultimate solution of their engineering failure problems.

VI. SURVEY AND OUTLOOK

Strength of materials, while firmly rooted in mathematics and physics, did not, at the stage of its development in the mid-1960s, offer so aesthetically satisfying an appearance as either of these two sciences. It was composed of many heterogeneous elements. There was no unique set of fundamental principles and assumptions from which satisfactory solutions to all problems can be derived. The link between the fundamental theoretical concepts derived from the theory of elasticity and the observations made in the testing of materials, and particularly in service, was missing.

As is perhaps to be expected in a science of such utilitarian character, it abounds in contradictions. In some respects it is highly theoretical, in many others purely empirical, and the link between theory and empiricism has become increasingly tenuous. The development of the science in the 20th century had become extremely centrifugal and there was little doubt that for some time, at any rate, its many diverse branches such as the theory of plasticity, fatigue, brittle fracture, metal physics and so forth would have to develop along more or less independent lines. It can only be hoped that at the end of such developments some new concepts may emerge which can serve as fundamental principles on which to build a unified science of deformation and fracture in which theory and experiment would no longer be in conflict.

In the 1960s the old concepts rooted in the theory of elasticity were being increasingly abandoned, and even such basic ideas as stress and strain were becoming inadequate for the description of observed phenomena.

Since the cardinal questions of fracture and deformation are so closely dependent on the methods of manufacture of materials, it

is inconceivable that progress can be made on a purely physical basis. Already strength of materials is closely linked with the science of metallurgy and the technologies of extracting, refining and fabrication of metals. This association must become closer. A science of the strength of materials, unable to account for the profound influence on strength properties of what may be termed manufacturing variables such as chemical composition, heat treatment and fabrication, will not serve the engineer. Metallurgy in turn must take note of the fact that the old mechanical properties which are still used for purposes of development, testing and acceptance of metallic materials have lost much of their previous importance, and that the significance of some of these properties in relation to the service conditions imposed on the material has become questionable.

Strength of materials is undergoing a profound though slow revolution. As in every revolution the first result is confusion. Since past theories no longer serve their purpose and new ones are only slowly emerging, the engineer, for a time at least, will be driven to solve his "strength of materials" problems on the basis of results obtained from *ad hoc* tests. In this way we have turned full circle because it was from such *ad hoc* tests, carried out by the early engineers, that the whole body of our knowledge has developed. See ARCHITECTURAL ENGINEERING; see also references under "Materials, Strength of" in the Index.

MATER MATUTA, goddess of Italian cult, probably most accurately described as a deity of the ripening of grain (Varro, in Augustine, *City of God*, iv, 8), although Lucretius (v, 656) makes her a goddess of dawn. Indeed the root *ma-* is found in both *mane* ("dawn") and *matutus* ("ripe"), but the agricultural explanation is perhaps more in keeping with a deity of Italian cult.

Her worship in Italy was both widespread and of ancient origin. Her temple at Rome, located in the Forum Boarium, was dedicated in 395 B.C. with antecedents going back traditionally to the time of Servius Tullius. The temple, long associated with Fortuna Virilis, an Ionic tetrastyle prostyle temple from the middle of the 1st century B.C., may represent a rebuilding. It is one of the best-preserved temples in Rome thanks to its conversion into the church of Sta. Maria Egiziaca in A.D. 872. That this temple is properly assigned to Mater Matuta, however, has been seriously questioned.

The festival of the Mater Matuta was held on June 11 and was marked by several unusual customs, among them that only free women of a first marriage might take part and that the women allegedly prayed not for their own children but for those of their sisters (but cf. H. J. Rose in *Classical Quarterly*, vol. xxviii, pp. 156 ff., 1934).

The goddess was later identified with the Greek Leucothea (Ovid, *Fasti*, vi, 473 ff.), who in turn was identified with Ino, wife of Athamas (q.v.). Thus she derives an association with the sea which did not originally belong to her.

See G. Wissowa, *Religion und Kultus*, 2nd ed., pp. 110-112 (1912); *Roman Questions of Philarch*, trans. by H. J. Rose, pp. 175 ff. (1924). (R. B. Lo.)

MATERNAL AND CHILD HEALTH is defined in preventive medicine as the field of work related to the physical, mental and emotional health of women immediately before, during and after childbirth, and of infants and young children. Emphasis is placed on the prevention of illness and its early correction when

it occurs. The development of maternal and child health services has taken place slowly as knowledge has grown and needs have changed; the term has had different meanings in different countries at different times, including the present. These services are now provided mainly by government and voluntary agencies, although they also can be obtained privately. The services vary in many ways but their objectives are always the same.

As maternal and child health services have evolved, their emphasis has shifted to meet new needs. For example, the infant death rate (i.e., in the first year of life) has been reduced greatly since 1900 but most of the reduction has taken place in the latter part of the first year and very little reduction has occurred during the first month, and especially in the first week. Consequently, maternal and child health programs now emphasize (1) prematurity; (2) childbirth accidents; and (3) continuous care of the mother during pregnancy, delivery and the days immediately following delivery. The concept and scope of maternal and child health (abbreviated MCH) have been widened as a result of an increased awareness of the effect of environment on the physical and mental health of infants and also because of recognition of the fact that the social and emotional atmosphere can be as disease-producing as unhealthy or dangerous physical surroundings. The group of health workers who provide MCH services has grown as the services have expanded and may include the family or public health physician, the family or public health dentist, the public health nurse (or health visitor), nutritionist, midwife, social worker, sanitarian, child psychologist, physiotherapist and health educator.

The leading cause of infant deaths throughout the world is diarrhea, especially when related to malnutrition. Progress in the control of diseases such as malaria, smallpox and cholera has revealed the vast reservoir of illness caused by underfeeding or bad feeding among children, especially those recently weaned and fed almost entirely on some locally popular cereal food, which often is coarse, bulky and unsuitable for the growing child.

All countries are concerned with the improvement of obstetrical practices. In many countries, midwives are widely employed and usually are licensed by the government.

National and international agencies have co-operated with local health agencies in the development of MCH services. The higher-level agencies have been most active in staffing and running training projects and seminars, in pediatric education in universities, in research into nutritional and other problems, in the provision of supplies and equipment and in arranging fellowships for the training of MCH workers.

This article first discusses maternal and child health from an international viewpoint and then examines the MCH services in the United States and in Great Britain. See also CHILD LABOUR; CHILDREN, DISEASES OF; CHILDREN, LAWS CONCERNING; CHILD WELFARE; DIET AND DIETETICS; INFANTS, CARE OF; NUTRITION; OBSTETRICS; PREGNANCY; PREVENTIVE MEDICINE; PUBLIC HEALTH; SOCIAL WELFARE.

INTERNATIONAL

Maternal and child health throughout the world is promoted and protected by various agencies through the application of current knowledge to the study and satisfaction of health needs of women and children.

In primitive societies the practice of curative and preventive medicine was and still is closely linked with religious beliefs and rites. Traditional knowledge expressed in the form of various rules and tabus frequently has a direct influence on the health of mothers and the survival and health of the child. In these societies the original aim was probably concerned more directly with the maintenance of the equilibrium and survival of the particular group than with the protection of the health of the particular individual. Some beliefs, e.g., those regarding foods that can or cannot be eaten during pregnancy or immediately after delivery, are definitely harmful to the mother and child. Others, such as the custom of separation of husband and wife for some time after delivery, or the regulation of sexual relations between the young couple by the elders of the family, ensure the spacing

of pregnancies and therefore a better start in life for the infant and better health for the mother.

Many of these ancient safeguards have broken down under the impact of western ideas, or as a result of the urbanization and industrialization of communities that were once rural. Where no adequate substitute has been found, such as safe and adequate artificial feeding to replace the traditional prolonged breast feeding, or feasible methods of family planning to replace the traditional methods of control, the health of the mother and child has suffered. The resulting conditions of malnutrition and deprivation have become, in many parts of the world, the chief child health problem.

The Industrial Revolution in western Europe, though it brought the beginnings of public health, was accompanied by a high death rate and much ill health and suffering among the children. It was by no means unusual to find a child five years old employed for a working day of 17 hours under miserable conditions.

The extent of the wastage of child life (ascertained through the collection and study of statistical information about births and deaths) was so shocking—for example, 200 infant deaths per 1,000 live births as compared with about 25 in the mid-1960s in Great Britain—that in several countries centres were set up to teach mothers the elements of child care and child feeding. From these centres (the *gouttes de lait* of Pierre Budin in France) and the "home health bringers" envisaged by Florence Nightingale, the maternal and child health services have developed in different ways in different countries, until they have spread out into all aspects of the lives of mothers and children both within and outside the family.

Death rates for children and for women in childbirth are very sensitive indexes of the health of a population. When a large number of children die before reaching school age, there is good reason to believe that this fact reflects generally insanitary conditions, lack of food, poor weaning and feeding practices and a high prevalence of infectious diseases. The object of maternal and child health programs is to bring these factors to light and to effectively control them. Conditions differ from country to country, but certain elements are common enough to allow distinction of three different situations, namely: (1) countries with well-developed public health services; (2) countries in the process of extending their services; and (3) countries where public health services were established relatively recently.

COUNTRIES WITH WELL-DEVELOPED PUBLIC HEALTH SERVICES

The original "infant welfare services" grew out of circumstances that made the supervision of the infant in the first year of life the most urgent need. These circumstances provided the possibility, at least theoretically, of the mother and child seeking and receiving the needed curative services from other sources. The first infant welfare services were therefore restricted mainly to education and preventive and noncurative activities, and there was often little co-operation between the persons who supplied these services and those responsible for looking after the mother during delivery and for mother and child in future illnesses.

Regular visits to mothers in their homes to advise on child feeding and care and general hygiene were, and still are, considered the basis of all maternal and child health work. The reporting of births enables the public health nurse to make her first contact with the mother soon after the birth of the child and to establish the relationship that continues through subsequent home visits and through the mother's attendance at the infant welfare centre. From these beginnings more comprehensive maternal and child health services have developed.

The Mother.—Prenatal services now ensure that the health, and especially the nutritional state, of the expectant mother is checked periodically; the avoidable complications of pregnancy are prevented or treated; preparations for painless childbirth are carried out; and through discussion groups or individual talks the mother is educated in the necessary skills and knowledge so that she can feed and care for her baby to the best of her ability. In some countries special foods are provided free or at minimum cost to pregnant women.

Most countries have also been concerned with ensuring skilled care and attention during childbirth through the provision of services by midwives trained to certain legally accepted standards or by the family doctor or obstetric specialist. In some countries, special medical attention for the newborn is also available. A domestic service has been organized in some countries to look after the family during the mother's confinement; in others the children are taken care of in holiday homes provided for this purpose.

Postnatal clinics provide a valuable opportunity for a check on the mother's health after delivery and for the early diagnosis and prevention of some chronic disabling conditions common in women. Family planning advice, given either by the MCH service staff or in special centres, is available to the woman as a form of health protection in many countries, especially in Europe and Asia.

A recent development is the marriage guidance service. Problems affecting the family and particularly the relationship between husband and wife are discussed and advice is given by trained counselors. The object is to avert dissolution of the family.

Infant and Child.—Well-developed services for the infant and child carried out in the health centre or during home visits include: (1) the regular checking of its growth and development; (2) informing the mother regarding the nutritional, physical and psychological needs of the child at various stages; (3) immunization against some of the infectious diseases; (4) the treatment of minor ailments; and (5) referral to the proper source for any special preventive or curative action. Dental care is also available at MCH centres in some countries. Home visits provide the best opportunity for education about the nutrition and general care of the growing child in its family, and the prevention of accidents in and around the home. A growing interest in the emotional development of the child has increased both the scope of the educational function of MCH services and the importance of visiting and studying the child in its familiar setting. MCH services are available to sick and well children alike, though with the general improvement in child health and in curative facilities for children in recent years, well-baby clinics have tended to increase. The sick child can receive treatment at the clinic, at home from the family doctor or pediatrician or at special children's departments in general or children's hospitals. It has been realized that the child is not just a small adult but instead is a growing individual with characteristics, needs and weaknesses peculiar to its stage of development. **Pediatrics**—the science of the diseases of children—has therefore been growing in importance during the 20th century as a specialization with its own knowledge and skills. Simultaneously, closer co-operation has developed between the clinician and the traditional MCH workers, whose knowledge of the child's background, gained through repeated home visits, and whose capacity for continuing surveillance of the child have proved indispensable.

In some countries milk and special health foods are available to the child through the MCH centre. In industrial areas of most countries, and during special times such as harvest in the rural areas of some countries, day care of the children of working mothers is provided by government or voluntary agencies in day nurseries under trained staff.

Children who for one reason or another have been deprived of an adequate home life are looked after in residential homes by trained house mothers and fathers. There is a general trend away from caring for these children in large institutions and toward placing them in small homes where they will regain their sense of belonging to a stable family group. Responsibility for their health supervision is usually undertaken by the MCH service personnel, as is also the health supervision of children in kindergarten or nursery schools.

Less direct but nonetheless important in their effect on the health of women and children are the various national measures for the protection of the woman who is having a child. These may take the form of maternity leave with full pay for employed women; assignment to lighter work during pregnancy; protection from loss of employment because of absence from work because of pregnancy and childbirth; and the provision of maternity allow-

ances or benefits in cash or goods. Family allowances, either as direct grants or as tax relief based on the number of children, are designed to contribute to the social and economic health of the family as a whole.

The School Child.—The health of the school child, when it is the responsibility of health or educational authorities, is supervised and protected by means of the school health service, school dental service and the control of the site and construction and sanitary condition of school buildings. Medical inspection on admission to school and regular inspections throughout the child's school life are compulsory in some countries and are carried out by qualified medical officers. Vaccination and immunization against various infectious diseases as well as treatment and the correction of defects may be provided free at special school clinics or sought by the parent elsewhere on the advice of the school medical officer or nurse. In some countries, dental clinics are a normal part of the school building. In others, children are referred to special clinics or to their own dentists. In rural areas mobile units carry the doctor or dentist and his equipment to the schools. Education of children regarding health matters, the development of good health habits during school life and the provision of adequate time and space for physical recreation are given varying emphasis in different countries. The mental and emotional health and development of school children have received increasing attention in recent years through the services of the educational psychologist and child guidance clinics.

School meals, which were supplied at the beginning of the 20th century to children in need or to those who for one reason or another could not obtain a midday meal, so proved their value in the improvement of the physical and mental health of the school child that they now form a regular feature of school life in countries such as Great Britain, the United States and Sweden.

Special services are provided by government or voluntary agencies for the care of the physically or mentally handicapped child in most countries—as well as convalescent or holiday facilities for the child in need of such short-term care.

COUNTRIES IN THE PROCESS OF EXTENDING THEIR SERVICES

In these countries, MCH services have already proved their worth in cities and urban areas, and in those areas the maternal and infant deaths have fallen considerably. Extension into the rural areas depends on an adequate supply of trained staff; this training generally emphasizes the inseparability of curative and preventive conditions and measures. Some change of emphasis is being given to the services provided. Present-day rural services demand a wider approach than was customarily taken in the past, when attention was concentrated on the infant's first year of life. The hitherto neglected preschool child is also in need of supervision and protection from accidents, infections and nutritional problems; these, it is now realized, cause high rates of sickness and death in this age group. Itinerant clinics have been found useful in the provision of MCH services to scattered rural communities, and the residents of these communities are being encouraged to build and develop their own health centres wherever possible. More use is being made of the auxiliary worker with a shorter training to complement the work of the fully trained doctor or nurse, especially in the field of home visiting and simple educational work with rural families.

COUNTRIES IN THE PROCESS OF DEVELOPING BASIC HEALTH SERVICES

Most of these countries are in the tropical or subtropical areas of the world where the hazards to maternal and child health include poverty, malnutrition, the diarrheal infections and numerous other infectious diseases such as malaria. Sanitary water supplies and sewage disposal are being developed, food production increased and the communicable diseases eradicated or brought under control by various means. In the field of child health, fragmentation of services is avoided by the establishment of an administrative division for maternal and child health in the national health organization. This unit is responsible for the supervision of the health of the mother from the antenatal period and of the

child until school-leaving age in a continuing and co-ordinated fashion. Urgently needed personnel such as doctors, public health nurses, midwives and their auxiliaries are being trained as rapidly as possible, often with the help of international organizations such as the World Health organization (WHO) and the United Nations Children's fund (UNICEF).

The assistance provided by WHO in the training of staff has taken various forms. One method has been to assign teaching staffs to medical nursing and midwifery schools for basic and post-graduate education. Sometimes it has been necessary to organize in-service training in demonstration and training centres; and many fellowships have been awarded for academic studies or study tours. The encouragement of the creation of chairs of pediatrics in medical schools—and their staffing by visiting professors for the initial years—is considered one of the most important ways in which WHO can assist countries to develop their services for children.

UNICEF has assisted in much of this work by providing equipment for training centres, schools of nursing and midwifery, teaching wards in hospitals, courses for traditional birth attendants and training stipends. The experience gained in field work is from time to time reviewed so that conclusions may be drawn to guide future plans.

Reliable statistics are available only from those countries where literacy and the general level of education have ensured that the basic information is given willingly and accurately. Until these standards become more general, information regarding the births, deaths and illnesses occurring in the population has to be sought by special surveys and investigations. The work of MCH services in the countries now developing their resources is largely educational—helping the mother to make the best use of the local amenities, soil, water, utensils and food in the care, nourishment and protection of her child. The separation of preventive and curative activities is impossible practically, as well as unacceptable to the people concerned. Indeed, a successful cure or curative campaign has proved one of the best means of encouraging the acceptance of the advice that so often conflicts with long-held beliefs about child rearing. In several countries, the help of anthropologists has been sought by public health and MCH workers to facilitate the development of services and methods acceptable to the indigenous culture. The traditional midwives have been encouraged to attend courses in which elementary concepts of hygienic midwifery practice are taught. Each country has developed its own particular form of rural MCH services, usually around the nucleus of a health centre staffed by at least one public health administrator, the midwife, the home-visiting public health nurse, a sanitarian officer and a village educator. The international agencies co-operate with national governments in the development of these services, in the staffing and running of training projects and seminars, in pediatric education in the universities, in research into nutritional and other problems, and in the provision of supplies and equipment and fellowships for the training of future national MCH workers. (V. W. W.)

THE UNITED STATES

Development.—Late in the 19th century, private agencies in several large U.S. cities opened stations to distribute pasteurized milk for babies in an effort to reduce infant mortality. This was the beginning of the infant welfare movement in the United States. As clean milk became generally available, the purpose of these stations changed. They became centres for continuous health supervision and the prevention of disease in infancy and early childhood; there, mothers could receive health guidance, advice on infant feeding and nutrition, and demonstrations from nurses in the care of the baby.

As the child health programs grew, recognition of the great value of prenatal care in the prevention of maternal and infant deaths became widespread. During the first decade of the 20th century organized prenatal nursing services and prenatal medical clinics began to be included in public health programs. In 1908 the New York city department of health established a division of child hygiene. This action by the largest city in the United States

accorded recognition to the importance of child hygiene and helped give impetus to a new era in maternal and child health.

The United States government in 1912 created the U.S. children's bureau, the first agency of its kind in any national government. According to the creating legislation, the bureau shall "... investigate and report . . . upon all matters pertaining to the welfare of children and child life among all classes of people, and shall especially investigate the question of infant mortality, the birth rate . . . and diseases of children. . . ." The bureau, initially a part of the department of commerce and labour, was placed in 1946 in the Social Security administration of the department of health, education and welfare.

An epoch in child health legislation was marked in 1921 with the passage of the Sheppard-Towner bill for the protection of mothers and infants. Administered by the children's bureau, this act provided for grants-in-aid to the states and thereby assisted in the creation of maternal and child health bureaus in many states. It lapsed in 1929 but laid the groundwork for the maternal and child health provisions of the Social Security act.

The Social Security act of 1935 authorized grants to the states for maternal and child health services and for services to crippled children. These grants are administered by the children's bureau. The purposes of the grants are to enable the states to extend and improve, especially in rural areas, (1) services for promoting the health of mothers and children and (2) services for locating crippled children and for providing them with medical and hospital care. Maternal and child health programs are administered by state health departments; services for crippled children are offered by the state agency designated by the state, usually the state health department.

Scope.—The maternal and child health program is primarily one of preventive health services, but a few states also provide some medical and hospital care for women with complications of pregnancy and for premature infants. The state programs include: maternity clinics that provide health supervision of expectant mothers by physicians, with advice by public health nurses and nutritionists as to hygiene and diet during pregnancy and lactation; well-child clinics that provide health supervision of children, vaccinations and advice to parents to help promote optimal growth and development; health services for school children; dental hygiene and prophylaxis; licensing and inspection of maternity homes; consultation to hospitals on maternity and newborn services; provision of incubators and hospital care for premature infants in special centres. There was much variation among the states in their programs.

During the mid-1960s medical prenatal care was provided in the state maternal and child health programs to about 280,000 expectant mothers annually. Medical and hospital care was provided annually to about 42,000 women with complications of pregnancy. Health supervision was provided yearly for 1,500,000 infants and preschool children at well-child conferences. School children examined annually by physicians numbered 2,440,000. Each year, about 3,000,000 children were immunized against smallpox, 4,225,000 against diphtheria, 2,700,000 against pertussis, 4,600,000 against tetanus, and 12,000,000 against poliomyelitis.

Increasing attention has been given to special programs for the care of premature infants, to the mental health aspects of pregnancy and child growth and development, to immunization, to provisions for postgraduate training of personnel, and to perinatal mortality (i.e., fetal and neonatal deaths). Since 1915, when the federal government began recording birth figures, the maternal mortality rate has declined 94% and the infant mortality rate has declined 75%. Much of the decline in death rates is due to improvements in education, hygiene and general living conditions; the greater availability of health and medical services; discoveries such as antibiotics; and hospital insurance. In the mid-1960s, 95% of all births in the U.S. took place in hospitals, and 97% of all births were attended by physicians.

The leading cause of infant deaths in the U.S. in the mid-1960s was prematurity; about 7.5% of all live births were premature. (In the United States a premature infant is defined as a live-born infant weighing 2,500 g. [5½ lb.] or less.)

In 1956 congress earmarked \$1,000,000 of the annual maternal and child health appropriation for use in assisting state health departments in developing demonstration programs to serve mentally retarded children. The interest in this work was so marked that other maternal and child health funds were added and by the mid-1960s all 50 states had developed programs. Most of these were organized around a mental retardation clinic staffed by a pediatrician, a medical social worker and a psychologist, with other specialists available. The programs provided diagnosis and evaluation of the child's expected achievement level, with particular attention to the young, more severely retarded children whose parents wished help in caring for them at home.

Much progress has been made in graduate training in public health for physicians, nurses, nutritionists, medical social workers and others. Financial support from the children's bureau was provided for maternal and child health teaching at certain schools of public health (e.g., Harvard, California, North Carolina, Pittsburgh, Johns Hopkins, Michigan, Minnesota), nursing and social work. Opportunities were made available for training in specialized clinical and public health fields such as prematurity, audiology, epilepsy, cerebral palsy, heart disease and childhood amputations of the limbs.

The crippled children's program was originally predominantly orthopedic. As the programs developed, they were extended to include children with other kinds of crippling conditions. The definition of crippling is determined by each state, so that there is some variation among the programs. In the mid-1960s more than 385,000 children received medical services each year in crippled children's clinics, hospitals and convalescent homes. About half of these children had an orthopedic handicap. The distribution of other major conditions included: cerebral palsy 9%; late effects of poliomyelitis 8%; hearing impairment 6%; burns and accidents 5%; cleft palate and harelip 5%; congenital heart disease 5%; rheumatic fever and heart disease 3%; and epilepsy 2%. About 30% of the total had congenital malformations. The number of children with congenital heart disease who received care showed marked increases; i.e., from 2,000 in 1950 to 8,000 in 1956 and 23,000 annually in the mid-1960s. This resulted from the considerable progress that has been made in developing new, highly successful surgical operations for treating these children. It was estimated that about 40,000 infants are born each year with some form of congenital heart disease.

The crippled children's program was expanded to include children with a wide variety of crippling conditions primarily because new methods of diagnosis and treatment became available. The number of epileptic children receiving medical services, though small, increased rapidly because new drugs became available for use in treatment. After ingenious new artificial hands and legs became available, a marked increase occurred in the number of children seeking care for the congenital absence of one or more limbs. The development of antibiotics and of the electronic hearing aid revolutionized the theory and practice of the diagnosis, prevention and treatment of hearing impairment. Programs for the conservation of hearing became widespread, with millions of children receiving audiometer tests each year. Hearing tests were developed for testing the hearing of infants. Because of the importance of helping the hard-of-hearing youngster to hear and speak early, many such children have been fitted with hearing aids at one year of age. This enabled them to learn normal communication instead of sign language and reduced the need for residential care. Increasing attention was being given to the effects of handicaps on emotional as well as on physical growth and development and to the use of measures that would reduce to a minimum the time young children are separated from their parents for surgery or other hospitalization.

Certain crippling conditions declined; e.g., osteomyelitis, mastoiditis, bone and joint tuberculosis and poliomyelitis. As a result, the proportion of children with congenital malformations increased. The trend among all programs was to broaden the scope of services to include more diagnostic services. There was also an increase in the number of diagnostic, treatment and rehabilitation centres for children where all pediatric and specialized

outpatient services could be provided. This had special significance for children with multiple handicaps. (AR. J. L.)

GREAT BRITAIN

During the last half of the 19th century there was a great improvement in the living conditions of the British people and some attention was being paid to the welfare of mothers and young children. Yet it was found at the end of the century that, in spite of a fall in the general death rate, the infant death rate had not fallen. In consequence, the years immediately preceding World War I saw great improvements in the care of infants and young children. Antenatal clinics were begun in London by Herbert R. Spencer in 1891 and in Edinburgh by John W. Ballantyne in 1901, while Frank Drew Harris set up a milk distribution centre in 1899. The Midwives act of 1902 inaugurated the state registration of midwives; the Notification of Births act of 1907 introduced the system of notification of births within 36 hours of their occurrence; and school health service came into being in 1907. Also in 1907, John F. J. Sykes, medical officer of health for St. Pancras, London, established a "school for mothers," consisting of a milk distribution centre and clinics for babies and older children. Local authorities and voluntary agencies, assisted by government grants, established further infant welfare clinics, where infants and young children were examined and mothers instructed in their upbringing; later these agencies founded many antenatal clinics, where expectant mothers were examined physically and were given instruction on how to maintain good health during pregnancy.

World War I delayed progress but the years between World Wars I and II saw the rapid development of all these services, so that by 1938 a comprehensive service was available for all expectant and nursing mothers and for children up to school-leaving age. During World War II, when food supplies were limited, special arrangements were made so that pregnant and nursing mothers and their young children were given priority in the distribution of milk and vitamin supplements. The wisdom of this policy was amply demonstrated by the obvious well-being of the mothers and children in this period and by the fact that the death rate among infants continued to fall through the war years. After the war the National Health Service act of 1946 established a general medical service that gave comprehensive cover for the whole population.

Maternity Services.—Under the National Health Service act, an expectant mother planning a domiciliary confinement can engage the services of a doctor, without fee, to look after her during pregnancy, confinement and puerperium; the services include a postnatal examination about the sixth week. The services of a domiciliary midwife are provided free for the same period by the local health authority. If the mother unexpectedly develops an abnormality during pregnancy or childbirth, the services of a consultant obstetrician are available to her free in her own home; if necessary, the obstetrician can be assisted by a medical and nursing team equipped to undertake emergency operative procedures.

When the mother has her baby in a hospital, all medical and nursing services and accommodation are provided free. In Great Britain approximately 35% of the babies are born at home and 65% in the hospitals. An ambulance service is provided free to transfer a mother to a hospital should an emergency arise or if she goes unexpectedly into labour. Following a normal confinement in the hospital the mother usually remains there for 10 to 14 days before returning home.

Unqualified women are not permitted to nurse women in pregnancy or childbirth. The length of training for a woman wishing to become a midwife is one year for state-registered nurses and 18 months for women who are not state-registered (see NURSING).

Whether the mother is confined at home or in a hospital, local authorities are empowered to provide the service of a domestic (who does not undertake nursing duties) in the home during pregnancy and the confinement or if there is illness in the home during that period or at any other time. The service may be provided free or at reduced cost.

Provided she satisfies certain insurance conditions, a mother is eligible for a maternity grant and, if she has been employed or self-employed until 13 weeks before the confinement, for a weekly maternity allowance for 18 weeks. If she has her baby at home she also receives a home confinement grant. (See SOCIAL SECURITY: *Social Insurance in Great Britain and the Commonwealth*.)

All expectant and nursing mothers, infants and young children are eligible for a supply of milk free or at reduced cost, as well as free orange juice, cod-liver oil and vitamin A and D tablets.

Postnatal Care.—On the 15th day after delivery, or as soon as possible thereafter, the mother is visited in her home by the district health visitor, a state-registered nurse who received six months' experience in midwifery and nine months' whole-time training in social medicine before taking the examination for the health visitor's certificate. She visits the mother at regular intervals thereafter and gives her advice and help on the upbringing of her child. She invites her to visit the local child welfare clinic, where her child may be examined by the clinic medical officer and where she can listen to health talks, join discussion groups or see health education demonstrations. The function of these maternal and child health clinics is primarily educational. If mother or child is found to be suffering from any disease or disability they are referred to their own family doctor or, if need be, and if the family doctor agrees, direct to a hospital.

Facilities for vaccination against smallpox and immunization against diphtheria, whooping cough, tetanus and poliomyelitis are also provided. Children attend these clinics and are medically examined at lengthening intervals until they are five years old unless they enter a nursery school at an earlier age, in which case they become the responsibility of the school health service. Any child between two and five years of age found to be suffering from a physical or mental handicap is referred to the school health service so that adequate arrangements can be made for his education before he reaches the age of five.

During his first year at school the child is examined by the school medical officer, assisted by the school nurse. Both are often the same persons who saw him in the child welfare clinic. This routine medical inspection is repeated when the child is eight or nine years old and again just before he leaves school. In the intervening period, if he is failing to make satisfactory progress either physically or mentally, he is referred to special clinics for the physically and mentally handicapped and for children who are mentally disturbed; there appropriate arrangements are made, with the approval of his family doctor, for him to receive the special care and treatment he requires.

Local authorities are required to make arrangements for the dental care of expectant and nursing mothers and of children up to school-leaving age but, owing to a shortage of dentists, this service was not fully developed by the mid-1960s.

A cooked meal is available free, or at reduced cost, for all school children. A family allowance is paid for each child in a family except the first child. The allowance in 1964 was 8s. for the second child and 10s. for each subsequent child. In the case of a widow eligible for widow's allowance, the allowance including the family allowance was 37s. 6d. a week for each child including the first. Children are eligible for these allowances until their 19th birthday, provided they are receiving full-time education.

The employment of a child under the age of 13 is prohibited. Over that age he may not be employed in such a manner as to be prejudicial to his health or otherwise render him unfit to obtain the full benefit of the education provided for him.

Finally, the youth employment service, which is part of the educational system, collaborates closely with the school medical officer to try to ensure that the young adolescent is placed in employment suitable to his mental and physical capacity.

The services that have been described are financed from central government funds and local taxes and are staffed by whole- or part-time employees of the local health authorities. General practitioners provide similar clinic facilities as part of their services to their patients and seek the assistance of the district health visitors in the social problems arising in their practice.

MATHEMATICAL INDUCTION, one of various methods of proof of mathematical propositions, based on the following principle.

The Principle of Mathematical Induction.—A class of integers is called hereditary if, whenever any integer x belongs to the class, the successor of x (i.e., the integer $x + 1$) also belongs to the class. The principle of mathematical induction is then: If the integer 0 belongs to the class F and F is hereditary, every non-negative integer belongs to F . Alternatively, if the integer 1 belongs to the class F and F is hereditary, then every positive integer belongs to F . The principle is stated, sometimes in one form, sometimes in the other; and as either form of the principle is easily proved as a consequence of the other, it is not necessary here to distinguish between the two. (See also NUMBER.)

The principle is also often stated in intensional form: A property of integers is called hereditary if, whenever any integer x has the property, its successor has the property. If the integer 1 has a certain property, and this property is hereditary, every positive integer has the property.

Proof by Mathematical Induction.—An example of the application of mathematical induction in the simplest case is the proof that the sum of the first n odd positive integers is n^2 ; that is, that

$$1 + 3 + 5 + \dots + (2n - 1) = n^2 \quad (1)$$

for every positive integer n . Let F be the class of integers for which equation (1) holds; then the integer 1 belongs to F , since $1 = 1^2$. If any integer x belongs to F , then

$$1 + 3 + 5 + \dots + (2x - 1) = x^2 \quad (2)$$

The next odd integer after $2x - 1$ is $2x + 1$, and when this is added to both sides of equation (2), the result is

$$1 + 3 + 5 + \dots + (2x + 1) = x^2 + 2x + 1 = (x + 1)^2 \quad (3)$$

Equation (2) is called the hypothesis of induction and states that equation (1) holds when n is x , while equation (3) states that equation (1) holds when n is $x + 1$. Since equation (3) has been proved as a consequence of equation (2), it has been proved that whenever x belongs to F the successor of x belongs to F . Hence by the principle of mathematical induction all positive integers belong to F .

The foregoing is an example of simple induction; an illustration of the many more complex kinds of mathematical induction is the following method of proof by double induction: To prove that a particular binary relation F holds among all positive integers it is sufficient to show, first that the relation F holds between 1 and 1; secondly that whenever F holds between x and y , it holds between x and $y + 1$; and thirdly that whenever F holds between x and a certain positive integer z (which may be made to depend on x), it holds between $x + 1$ and 1.

The logical status of the method of proof by mathematical in-

duction is still a matter of disagreement among mathematicians.

Giuseppe Peano (*q.v.*) included the principle of mathematical induction as one of his five postulates for arithmetic (see POSTULATE). Many mathematicians agree with Peano in regarding this principle just as one of the postulates characterizing a particular mathematical discipline (arithmetic) and as being in no fundamental way different from other postulates of arithmetic or of other branches of mathematics.

Henri Poincaré (*q.v.*) maintained that mathematical induction is synthetic and a priori; that is, it is not reducible to a principle of logic or demonstrable on logical grounds alone, and yet is known independently of experience or observation. Thus mathematical induction has a special place as constituting mathematical reasoning par excellence, and permits mathematics to proceed from its premisses to genuinely new results, something that supposedly is not possible by logic alone. In this doctrine Poincaré has been followed by the school of mathematical intuitionism (see MATHEMATICS, FOUNDATIONS OF) which treats mathematical induction as an ultimate foundation of mathematical thought, irreducible to anything prior to it, and synthetic a priori in the sense of Immanuel Kant (*q.v.*).

Directly opposed to this is the undertaking of Gottlob Frege (*q.v.*), later followed by Alfred North Whitehead and Bertrand Russell (*qq.v.*) in *Principia Mathematica*, to show that the principle of mathematical induction is analytic, in the sense that it is reduced to a principle of pure logic by suitable definitions of the terms involved. A sketch of the method, especially the definitions, by which this is to be accomplished is given under Frege's name in the article LOGIC, HISTORY OF.

Transfinite Induction.—A generalization of mathematical induction applicable to any well-ordered class or domain D , in place of the domain of positive integers, is the method of proof by transfinite induction.

The domain D is said to be well-ordered if the elements (numbers or entities of any other kind) belonging to it are in, or have been put into, an order in such a way that: 1. no element precedes itself in order; 2. if x precedes y in order, and y precedes z , then x precedes z ; 3. in every non-empty subclass of D there is a first element (one that precedes all other elements in the subclass). From 3. it follows in particular that the domain D itself, if it is not empty, has a first element.

When an element x precedes an element y in the order just described, it may also be said that y follows x . The successor of an element x of a well-ordered domain D is defined as the first element that follows x (since by 3., if there are any elements that follow x , there must be a first among them). Similarly, the successor of a class E of elements of D is the first element that follows all members of E . A class F of elements of D is called hereditary if, whenever all the members of a class E of elements of D belong to F , the successor of E , if any, also belongs to F (and hence in particular, whenever an element x of D belongs to F , the successor of x , if any, also belongs to F).

Proof by transfinite induction then depends on the principle that if the first element of a well-ordered domain D belongs to a hereditary class F , all elements of D belong to F .

One way of treating mathematical induction is to take it as a special case of transfinite induction. For example, there is a sense in which simple induction may be regarded as transfinite induction applied to the domain D of positive integers. But the actual reduction of simple induction to this special case of transfinite induction requires the use of principles which themselves are ordinarily proved by mathematical induction, especially the ordering of the positive integers, and the principle that the successor of a class of positive integers, if there is one, must be the successor of a particular integer (the last or greatest integer) in the class. And there is therefore also a sense in which mathematical induction is not reducible to transfinite induction.

The point of view of transfinite induction is, however, useful in classifying the more complex kinds of mathematical induction. In particular, double induction may be thought of as transfinite induction applied to the domain D of ordered pairs (x, y) of positive integers, where D is well-ordered by the rule that the pair

(x_1, y_1) precedes the pair (x_2, y_2) if $x_1 < x_2$ or if $x_1 = x_2$ and $y_1 < y_2$.

MATHEMATICAL INSTRUMENTS. The increasing use of mathematics, both as a language for expressing the problems of science and industry, and as a tool for dealing with those problems, has spurred the development of rapid and economical means for obtaining answers to the mathematical problems posed. In a broad sense, any device capable of supplying such answers is a mathematical instrument, which may be defined as a device in which measurable physical quantities such as distances between marks on a rule, electric currents in wires, etc., are used to represent mathematical quantities, and the physical laws governing the device correspond to a set of mathematical relations for which a solution is sought.

The following discussion deals with forms of mathematical instruments (many of which continue to be used in the 1960s) that preceded the development of more recent devices described under **COMPUTER**.

Classification of Instruments.—Mathematical instruments have been constructed of a great variety of elements, but despite the diversity of the mechanisms employed most of the instruments in common use fall into the three main categories discussed below, which are defined by the characteristic mathematical operations they perform. One group solves finite equations, either algebraic or transcendental and in typical instances makes use of cams, linkages, gears or variable electrical elements to establish the required connections among the given variables. A second group evaluates integrals and derivatives by means such as wheels rolling on surfaces of various shapes, or charges and currents in electrical circuits or the quantity of light transmitted thru specially prepared optical media. The third group solves partial differential equations and may employ elastic membranes, electric currents in conducting sheets or polarized light.

INSTRUMENTS FOR THE SOLUTION OF FINITE EQUATIONS

Tide Predictor.—The behaviour of the tides at any given port is characteristic of the behaviour of many physical variables. It is found that the height of the tides is a function of time which can be formed by adding together a number of sinusoidal or simple harmonic functions of time, the periods of the latter agreeing with those of the apparent rotation of the sun and moon. Thus the height of the tide is representable by a trigonometric sum, the value of which can be calculated once the amplitudes of the various sinusoidal components have been determined for the port in question. To avoid the labour of computation, Lord Kelvin, in 1872, built his tide predictor, which is preserved in the Science Museum in the Kensington borough of London. In Kelvin's model, eight trigonometric components are generated by eight pulleys carried on axes at the ends of eight cranks of adjustable lengths. Four pulleys are carried on the upper and four on the lower side of a rectangular wooden frame. A cord, fixed at one end, passes over alternately under the lower and over the upper pulleys, and at the other end carries a weight and marker. The centre of each pulley other end carries a weight and marker. The centre of each pulley can describe a circular motion of adjustable amplitude, which circular motion is equivalent to the sum of two simple harmonic or sinusoidal motions, one vertical and the other horizontal. The horizontal component of the circular motion moves the cord out of its vertical position, but if the radius of the circle described by the centre of each pulley is a small fraction of the distance between the lower and upper pulleys, the effect of the horizontal component is small, and the principal effect on the cord is that of

the sinusoidal vertical component. The hanging weight will therefore perform a motion which is the sum of the constituent vertical motions of the pulleys.

In the first complete working machine made on the lines of Kelvin's original model, ten components are added, and the curve representing a year's tide for any port can be drawn in about four hours. In later machines of larger capacity, the horizontal motion of the pulleys was eliminated by the use of scotch crossheads, the portion of the wire between upper and lower pulleys remaining always vertical. In a machine made in 1924 and located at Liverpool, there are 26 components; in an American machine completed in 1910 there are 37 components, and the tidal curves for seven years can be run off in 12 hours.

Harmonic Synthesizer.—While height of the tide is representable by a trigonometric sum having periods that agree with those of the sun and moon, certain other physical functions such as the voltage produced by an alternating-current generator, are representable by sums of components with periods which are all submultiples of a single fundamental period. Several harmonic synthesizers have been built along the lines of the Kelvin tide predictor described in the preceding paragraph but modified so that the rotational speeds of the cranks carrying the pulleys are in the ratios 1:2:3 etc. and hence the periods of the component motions are submultiples of a fundamental period.

A harmonic synthesizer was designed by Albert A. Michelson and Samuel W. Stratton which differs in principle from the Kelvin machine in that components are added by the summation of forces due to a set of springs, instead of the summation of the displacements of pulleys. In 1897 a machine with 20 components was made, and in the following year one with 80 components. Each component is generated by an element containing an eccentric (near the base of the machine) which communicates a sinusoidal motion to the end of a horizontal lever. The foot of a long rod may be clamped in any position along the lever, the amplitude of the motion which the lever communicates to the rod being therefore proportional to the distance from the fulcrum of the lever to the foot of the rod. The upper end of the rod actuates a lever which in turn extends a small spring. The springs of all the elements are attached to one edge of a wide balance lever and the sum of their forces is balanced by the action of a single very stiff countspring.

The motion of the balance lever is accordingly nearly proportional to the sum of the motions of the rods, and this resultant motion is conveyed to a pen which draws a graph on a paper carried by a traveling plate.

Polynomial Solvers.—In the design of communication circuits, and in the determination of the stability of dynamical systems, it is important to know the values of the roots of polynomials such as

$$P(z) = A_0 + A_1z + A_2z^2 + \dots + A_nz^n$$

that is, it is required to find the values of z which make $P(z) = 0$. The theory of functions of a complex variable shows that if one draws the curve whose rectangular co-ordinates are derived from the coefficients of the polynomial by the relations

$$\begin{aligned} x &= pA_1 \sin \theta + p^2A_2 \sin 2\theta + \dots + p^nA_n \sin n\theta \\ y &= A_0 + pA_1 \cos \theta + p^2A_2 \cos 2\theta + \dots + p^nA_n \cos n\theta \end{aligned}$$

and if this curve wraps itself k times around the point $x=0, y=0$, then there are k roots with absolute values less than p .

The graph defined by x and y is drawn by an instrument devised in 1937 by Thornton C. Fry and R. L. Dietzold and named by them the isograph. Mechanically, this machine is a ten-component harmonic synthesizer of the Kelvin type, in which the sine components are added and applied to move a pencil, while the cosine components are added separately from the sine components and caused to move the table on which the pencil traces the curve (x, y) , these two motions taking place at right angles to each other.

In operation, a value of p is chosen; the coefficients are multiplied by the appropriate powers of p , and the products are set on the synthesizer. A curve (x, y) is drawn by the machine, and

the number of roots with absolute values less than p is determined by inspection of the curve. A new value of p is taken, and the process repeated. If the number of roots counted has changed, then at least one root lies between the two values of p . By successive trials, the region containing a root is thus narrowed down as far as may be desired, within the limits of error of the machine. While the isograph is applicable only to polynomials with real coefficients, S. Leroy Brown has employed his harmonic synthesizer-analyzer in a similar way to the search for roots of polynomials with complex coefficients.

A polynomial solver in which the synthesis is performed electrically was designed by H. C. Hart and Irvén Travis in 1937. In this machine, the components are represented by electrical voltages generated by a set of adjustable transformers. The transformers are built in a form similar to that of a motor, and are so designed that the amplitude of the voltage supplied by them is proportional to the sine of θ , the angular position of the rotor shaft, and to the voltage applied to the primary windings. The shafts of the set of transformers are so geared that their rotations are proportional to the integers, 1:2:3, etc. The primary voltages are made proportional to the coefficients $p^k A_k$, and the secondary voltages are added together by connecting the transformer secondaries in series. A set of potential dividers, properly interconnected, supplies voltages proportional to the appropriate powers of p multiplied into the coefficients A . In operation, both p and θ are adjusted by hand until the values of the voltages representing the sine sum and the cosine sum are simultaneously zero. The values of p and θ at which this null point is found define a root which is, in complex exponential form,

$$z = pe^{j\theta}$$

Still another form of polynomial solver was proposed and built by Felix Lucas, in 1887. The operation of this device depended upon certain theorems in the theory of functions of a complex variable and in the theory of the flow of electric currents in sheets of conducting material. In Lucas' device, electric currents whose values are calculated from the values of the coefficients of the polynomial, are applied to certain points in a large (theoretically unbounded) sheet of material. The complex plane for z is plotted on the sheet and the required roots of the polynomial are read off this plot at the points where the current vanishes. Lucas found that the errors introduced by neglecting the finite size of his sheets are appreciable but this difficulty can be avoided by throwing one-half the infinite z -plane into a finite region before mapping.

Linear Algebraic Equation Solvers.—A great variety of engineering problems, such, for example, as those of computing stresses in structures, electric currents in distribution networks, and correlations among statistical data, reduce to the solution of a system of linear algebraic equations, in the form

$$\begin{aligned} C_{00} + C_{01}x_1 + C_{02}x_2 + \cdots + C_{0n}x_n &= 0 \\ C_{10} + C_{11}x_1 + C_{12}x_2 + \cdots + C_{1n}x_n &= 0 \\ \vdots &\vdots \\ C_{n0} + C_{n1}x_1 + \cdots + C_{nn}x_n &= 0 \end{aligned}$$

where the C 's are given numerical values, and it is required to find the values of the x 's which satisfy the equations.

Much ingenuity and effort has gone into the problem of designing mechanisms to solve this problem, and many theoretically correct designs have been produced. In general, however, it may be said that the low accuracy obtainable together with the time required to set up the data of problems have prevented these mechanisms from finding extensive application. Many of them depended upon balances among the forces due to springs or weights, or upon the level sought by a fluid in interconnecting vessels.

A linear equation solver which depends upon the addition of mechanical displacements was reported by John B. Wilbur in 1936. With this solver ten unknowns can be found, usually to within 1% of the value of the largest unknown.

In 1933, R. R. M. Mallock described an electrical machine for solving linear systems. An improved version of Mallock's instru-

ment made by the Cambridge Instrument Co., will solve for ten unknowns to 0.1% of the largest, and will also give a least-squares solution of a set of inconsistent equations. The Mallock machine consists of sets of electrical transformers, one for each unknown, and a set of closed electrical circuits, one for each equation. The coefficients are introduced by adjusting the number of turns each circuit makes about each transformer core.

INSTRUMENTS WHICH INTEGRATE AND DIFFERENTIATE

Planimeter.—One of the simplest applications of integration, and one of the earliest historically, is the determination of the area under a curve. If x and y are the rectangular co-ordinates of a curve defined by $y = f(x)$, then the area A bounded by the curve, the two abscissas x_1 and x_2 , and the axis $y = 0$, is the integral of $f(x)$ taken from x_1 to x_2 :

$$A = \int_{x_1}^{x_2} y \, dx$$

Frequently, the area under a curve represents some quantity of engineering interest and it becomes worth while to make use of an instrument for the rapid determination of that area. To quote only one instance out of many, the area of the curve drawn by a steam-engine indicator is used as the basis for determining the efficiency of the engine.

The invention in 1814 of the first instrument for the direct measurement of the area bounded by an irregular curve is attributed to the Bavarian engineer, J. H. Hermann, and was followed by the invention of similar instruments by numerous men, notably by Tito Gonella of Florence (1824), the Swiss engineer Johannes Oppikofer (1826), and Wetli of Zürich (1849). An example engraved, "Patent von Wetli a Starke, no. 103," which was constructed in 1860, consists of a rotatable horizontal circular disk on which the registering roller rests. The disk is mounted on a frame supported by three grooved wheels, which can roll on three parallel rails. Beneath the disk and mounted on the frame is a horizontal rod held between two pairs of guide rollers, so that it can move in a direction at right angles to the rails. By means of a thin wire wound round the axle of the disk and attached to the ends of the rod the disk is given an angular movement proportional to the longitudinal displacement of the rod. As the tracing point attached to one end of the rod is guided along the curve whose area is to be measured, the distance between the centre of the disk and the plane of the registering wheel is always proportional to the ordinate of the curve. The number of revolutions of the registering wheel is therefore a measure of the area.

J. Clerk Maxwell in 1855 designed a planimeter in which pure rolling was substituted for the undesirable partial sliding of the register wheel, but the instrument was never constructed. James Thomson in 1876 investigated the same problem, and in attempting to simplify Maxwell's mechanism evolved his disk, sphere and cylinder combination which has since been widely used in other mechanisms.

Jacob Amsler, about 1854, invented his polar planimeter which because of its simple construction and low price very soon came into extensive use. In using a polar planimeter manufactured about 1875, a weighted point is fixed and a tracing pointer is guided around the figure whose area is to be measured. The difference of the readings on a graduated roller before and after this operation gives the area of the figure in units depending on the radius of the tracing arm.

Integrators.—A generalized form of planimeter called an integrator was invented by Amsler in 1856. In addition to the area of a figure, this device also measures the moment, $\int y^2 dx$, and the moment of inertia $\int y^3 dx$ of the figure about the axis, $y = 0$. The instrument is carried by a pair of wheels moving in a straight groove in a long steel bar, and a counterweight is provided. If the tracing point is guided so as to describe the outline of a plane figure, the graduated roller attached to the swinging arm will register the area of the figure, as in the Amsler planimeter. An outer roller will register the moment of the areas about the

axis of rotation of the instrument. The moment of inertia about the same axis is deduced from the readings on the first roller and the inner one.

In 1887, Capt. Andreas Prytz invented the simple knife-edge or hatchet planimeter. In its original form it consisted of a metal bar, bent at right angles at both ends, one end of which (the tracer) was pointed, and the other was in the form of a curved knife-edge. In using the instrument, a point is chosen near the centre of the area to be measured, and a radial line is drawn from that point to the boundary. The tracer of the instrument is placed at the chosen point, and the hatchet pressed into the paper to form a dent. The tracer of the instrument is then made to follow the radial line and the boundary curve, ultimately returning to the centre point of the area along the same radial line. The hatchet is again pressed into the paper to form a dent. If AB , AB' be the initial and final positions of the arm, the area described is equal to the length of the arm multiplied by the length of the arc BB' .

Integragraphs.—In mathematical language, the planimeter measures the value of a definite integral; for certain applications it is necessary to know the indefinite integral of a function defined by a graph; that is, an instrument is required which will

ently by Abdank Abakanowicz about the same time as that of Boys. This instrument has been made in considerable numbers, with modifications and improvements in design and construction, by Coradi of Zurich.

Harmonic Analyzers.—Jean B. J. Fourier, in his study of the transmission and diffusion of heat, first made use of the simplification which often occurs when a complicated function or curve is represented as the sum of a number of simple harmonic or sinusoidal components. The importance of such a representation has increased with the years, and the measurement of the harmonic components in empirically given data is of importance to the study of communication lines, of electrical power machinery, of mechanical vibrations and noise, of musical instruments, and even in the theory of prediction of statistical data.

While much of the analysis in these fields is carried out by numerical processes, some is done by harmonic analyzers. It is shown in the theory of harmonic analysis (*q.v.*) that under suitable restrictions on the function analyzed a periodic function $f(x)$ can be represented by the series

$$f(x) = \sum (A_n \sin nx + B_n \cos nx)$$

where the amplitudes A_n , B_n are determined by

$$A_n = \frac{1}{\pi} \int_0^{2\pi} f(x) \sin nx \, dx$$

$$B_n = \frac{1}{\pi} \int_0^{2\pi} f(x) \cos nx \, dx$$

It is the object of the harmonic analyzer to determine the coefficients A_n and B_n by a rapid and easy process. There are harmonic analyzers of at least three basically different types. The earliest is an extension of the planimeter and integrator; more recent analyzers have been constructed in which the function is represented on photographic film, and the analysis performed photoelectrically; still other analyzers have converted the given data into electric currents and applied the extensive mechanisms in existence for the analysis of such currents.

Lord Kelvin in 1876 was the first to invent an instrument for performing harmonic analysis mechanically, by an adaptation of the disk-sphere-cylinder mechanism invented by his brother, James Thomson, in 1876. The first completed instrument designed by Kelvin and used for the harmonic analysis of tidal observations, embodies 11 sets of the disk-sphere-cylinder combination, one for each harmonic to be measured. The curve to be analyzed is wound on a central cylinder, and the simple harmonic motions of the proper periods are communicated to the disks by suitable gearing. The bar to which the tracer is attached has a series of forks which embrace the spheres. In actual use, the tracer is made to follow the curve, and the readings on the different integrating cylinders give the required coefficients. An improved form of the analyzer was invented by O. Henrici and Abraham Sharp in 1894.

A different type of harmonic analyzer in which the principle of action is based on William K. Clifford's graphic method of harmonic analysis, was invented by O. Mader in 1909. Essentially Mader's instrument consists of a gear and linkage which, as a pointer traces a given curve, cause a point on the gear to describe a transformed curve; the area enclosed by the transformed curve is measured by an ordinary polar planimeter, and is proportional to the required harmonic coefficient. In using the Mader instrument, a guide ruler which forms part of the machine is placed parallel to the base line of the curve to be analyzed, and the tracer of the planimeter is placed in one of two holes in the gear. For each harmonic to be found there is an appropriate gear with two indentations in its face. To find the sine coefficient, the tracer of the planimeter is placed in one of the indentations while the analyzer traces the given curve, while to find the cosine coefficient, the tracer of the planimeter is placed in the other. The Mader instrument measures only one harmonic at a time, as contrasted with the Henrici analyzer which measures several simultaneously.

Several analyzers have been devised to use optical and photo-

BY COURTESY OF KEUFFEL AND ESSER COMPANY

INTEGRAPH THAT WORKS ON THE PRINCIPLE OF THE ABDANK-ABAKANOWICZ DEVICE. AS IT TRACES THE OUTLINE OF A GIVEN CURVE (BELOW), THE INTEGRAPH AUTOMATICALLY DRAWS THE INTEGRAL CURVE (ABOVE)

draw the integral curve corresponding to any given curve. One integragraph was invented by Charles V. Boys in 1881.

For any value of x the steepness $\frac{dz}{dx}$ of the curve drawn by the instrument is proportional to the ordinate (y) of the given curve for the same value of x . Thus the integragraph solves the relation

$$\frac{dz}{dx} = y, \text{ or } z = \int y \, dx$$

The framework of Boys' instrument is a kind of T-square (which can slide along a horizontal straight edge) carrying a centre B which moves along the x axis of the given curve. A rod passing always through B carries a pointer A which is constrained to move in a vertical line ee of the T-square; A can then be made to follow any curve. The distance from B to ee is a constant k ; therefore the inclination of the rod AB is such that its tangent is equal to the ordinate of the given curve divided by k . Thus AB has always the inclination of the required curve.

The integral curve is generated by a three-wheeled cart, whose front wheel C is steerable. By means of epicyclic gearing this wheel is kept parallel to AB and can move only in the direction of its own plane. As C is always in the line ee produced, the wheel draws the required curve when allowed to pass over carbon paper.

The first integragraph made commercially was invented independ-

electric means. One such device was designed by H. C. Montgomery in 1939. To use Montgomery's analyzer, the curve to be analyzed is drawn or photographed on a transparent film, and the area of the film on one side of the curve is blacked out to make it opaque. A set of standard films is available in which the "density" varies along the length of the film. Thus when light falls on any part of the film, the fraction of the light transmitted is proportional to the function $C + D \sin \pi x$, where C and D are constants and x is the distance from a reference mark to that part of the film where the light falls. If the film carrying the curve to be analyzed is superposed on the standard film, then the quantity of light transmitted through any transverse strip of the two superposed films is proportional to the width of the clear part of the one film multiplied by the transmission ratio of that strip of the standard film. Except for the appearance of the additive constants in the factors, this product is the integrand in the definition of the required harmonic coefficient, and the total light transmitted by the entire length of the films is the integral of the product. The total light is measured by photocells, and from this quantity the harmonic component can be deduced. The operation of the instrument is largely automatic, and 30 harmonics can be measured in about a minute and a half.

Differential Analyzer.—The most frequently encountered mathematical problems of engineering and physics are expressed in terms of differential equations, either ordinary or partial. The methods and theory of the solution of ordinary differential equations have received treatment at the hands of many of the masters of mathematics, but there are comparatively few of the differential equations arising in practice that have solutions expressible in terms of a finite number of the elementary functions: sines, cosines, Bessel functions and so forth. Often in the applications of differential equations to engineering, formal solutions may not be necessary or even desirable if a numerical or graphic solution is obtainable. To calculate the latter kind of solution a number of differential analyzers have been constructed in the United States, Great Britain and other countries. Besides solving numerous problems in the design of electrical machinery, in the study of the scattering of electrons by atoms and the determination of the paths of electrons in the field of magnetic dipoles, in the treatment of the performance of automatic industrial control systems and of transients in electric lines, in the determination of the energy exchanges between gases and solids, and in the study of the boundary layer motion of viscous fluids, to mention a few items, the analyzers found extensive use in World War II in the computation of thousands of ballistic trajectories.

The development of the differential analyzer is largely due to Vannevar Bush and his associates at the Massachusetts Institute of Technology in Cambridge. In 1927 Bush and others completed and described a product integrator or continuous integrator which was a forerunner to the analyzer. This device solved differential equations of the form

$$\frac{d^2y}{dx^2} = f_a(f_1 + f_2)$$

where the f 's are functions of x ordinarily given in the form of graphs.

In 1928 Bush published a description of the first differential analyzer capable of solving a broad class of differential equations. Many minor modifications have been made in the detailed mechanisms of this machine, and more or less exact copies have been produced for use at educational institutions and industrial laboratories throughout the United States, Great Britain and Europe.

The Rockefeller differential analyzer, dedicated in Nov. 1945, represented a considerable advance over the original model partly in refinement of elements but principally in the speed and convenience of means for setting up and controlling the operation of the analyzer.

The basic elementary device in the differential analyzer is the disk and wheel integrator, which appeared first in the early

planimeters. Its function is to perform the integration,

$$z = \int y \, dx$$

where, in the integrator, x is the angular displacement of the disk, y is the distance of the integrating wheel from the centre of the disk, and z is the resulting angular displacement of the integrating wheel. The addition of two quantities, x and y , each represented by the angular displacement of a shaft, is performed by a mechanical "differential" or adder, so arranged that a third shaft is rotated through an angle equal to the sum, z , of the first-mentioned displacements:

$$z = x + y$$

Multiplication by a constant is accomplished in the analyzer by appropriate gearing; thus, if k is the gear-ratio between a shaft representing a variable x and another shaft representing a variable y , then

$$y = kx$$

Arbitrary or empirical functions are introduced by means of "input tables," on which are plotted the necessary functions in graphic form.

The solutions which result from the operation of the differential analyzer appear in the form of graphs drawn by the analyzer on output tables, or in the form of numerical values printed by the machine at predetermined intervals.

The original differential analyzer is entirely mechanical in construction, all connections between the computing elements being made by means of shafts and gears which are mounted on a bed-plate approximately 4 ft. wide by 18 ft. long. In using the differential analyzer, the equations to be solved are first written as a set of equations each of which may contain an integration, an addition, a multiplication by a constant, or a functional relation like $y = f(x)$. From the equations, a working diagram is made in which symbolic representations of shafts, integrators, adders and gears appear. The variables of the equations are equated to the rotations of corresponding shafts with suitable proportionality factors, and the performance of each mathematical operation in the equations is assigned to a particular one of the elementary mechanisms. The shafts, gears, integrators and other elements of the analyzer are set up in accordance with their symbolic representation on the working diagram.

In the Rockefeller analyzer, shaft rotations are converted by means of rotating electrical condensers into electrical signals which control motors in such a way that the shafts driven by the motors follow very closely the positions of the controlling shafts. Electrically operated switches steer the control signals as required from place to place, thus dispensing with the necessity of connecting shafts by mechanical means. All the information needed to set up the analyzer for a given problem is coded and punched in paper tapes which automatically arrange the electrically operated switches as required, in a few minutes.

Weiss Integrator.—When rapid approximate solution of a system of linear differential equations with constant coefficients is required, a device invented in 1944 by H. K. Weiss is applicable. By well-known analytic means, such systems of differential equations can be solved with the aid of any device which will solve the simple differential equations

$$a \frac{dy}{dx} - by = f(x)$$

$$a \frac{d^2y}{dx^2} - b \frac{dy}{dx} - cy = f(x)$$

where a , b and c are real numbers.

Weiss' integrator for the former of these equations consists of an arm at one end of which is a roller fitted with an inking pad so that it traces out the graph of y , when an adjustable pointer on the arm is made to follow a graph of $f(x)$. The integrator for the second differential equation consists of a pair of arms with a parallel linkage between them; each arm is equipped with a roller, one of which is inked and traces the graph of y . The lengths of the arms and the scale of $f(x)$ must

be chosen so that the angles of the arms with the axis of x remain small throughout the solution.

INSTRUMENTS FOR THE SOLUTION OF PARTIAL DIFFERENTIAL EQUATIONS

All mathematical instruments are in a sense analogues of the physical situation for which they are intended to furnish a solution, but in the case of certain devices which are used to obtain the solution of partial differential equations the analogy is very close. A typical device of this kind is that used to solve the differential equations of the potential in electronic tubes, and to predict the paths followed by electrons moving under the influence of that potential. It is shown in the potential theory that the electric potential and the displacements of a stretched elastic membrane satisfy the same partial differential equation. Several industrial and educational laboratories concerned with the study and design of electron tubes have developed instruments consisting of rigid frames with circumferential clamps, which maintain a practically uniform tension in a sheet of rubber stretched across the frame. The sheet being horizontal, its vertical displacements satisfy the potential equations, and when suitable boundary values are introduced by means of supporting blocks or clamps, the sheet supplies the solution to the potential problem with specified boundary conditions. A light marble rolled on the rubber sheet follows the path which an electron would in an electric potential field.

MATHEMATICAL MODELS. The child's box of wooden blocks is probably his earliest acquaintance or contact with mathematical conceptions. These concrete forms of the cube, or the more complete selection of geometrical solids comprising cubes, prisms and cylinders, appeal to the latent mathematical talent of the child, just as the abacus or counting-bead frame may stir some understanding of arithmetic.

The child learns that such forms as the cube and prism have many special properties which may, when used in right proportions, make them some of the most pleasing forms of architecture. The simple doubled cube, for example, provides an exquisite form of pedestal; in fact, the inherent beauties of the rectangular prism furnish a valuable architectural theme; also, by means of models it is possible to illustrate to the practical man a conception which may be ordinarily grasped only by a gifted or trained mathematical thinker.

A knowledge of plane geometry acquired without any reference to models may be said to flatten out habits of thinking and make it difficult at a later stage of mathematical education to explore space of three dimensions.

Plane Geometry.—Some early editions of Euclid (*q.v.*) had diagrams intended to be cut and folded, and a work by Cowley of 1752, *New and Methodical Explanations of the Elements of Geometry*, included pieces of cardboard for building various models. As talented a thinker and philosopher as Herbert Spencer appreciated the advantage of a model; in a letter to his father in Jan. 1839 he mentioned his self-set task of regular, daily and systematic study of mathematics, and wrote, "I have found out the grand principle of the projection of shadows and I feel almost certain of its correct-

ness. To make myself still more satisfied I have made a model in pasteboard and I find that the real shadow is as exactly as possible what I had made it by projection."

Intuitive Geometry.—A valuable aid in training mathematical beginners is to cut cardboard equilateral triangles of the same size. The single triangle represents the plane figure; several piled with corresponding edges coplanar and corresponding corners collinear illustrate the triangular prism; while four of them placed with pairs of edges coinciding, one of them being used as a base, give the tetrahedron, the first of the regular solids. The student may thus, by an inductive process, quickly arrive at the complete family of the five regular solids (see *SOLIDS, GEOMETRIC*).

Simple models of this nature may be used to demonstrate common practical problems involving important principles relating to regularity and maximum and minimum values; for example, that a triangle of given perimeter encloses the greatest area when it is equilateral, or that a tetrahedron of given surface area encloses the greatest volume when it is regular.

Polyhedrons.—An important application of this style of model can be made by drawing a cluster of seven equal hexagons, one surrounded by six others. Cut along the 18 boundary lines of the cluster, along the six sides of the central hexagon (which can then be discarded) and along just one of the remaining (radial) lines of the ring of six hexagons. Then cut halfway through and fold back or crease the rest of the radial lines. The paper may now be folded to illustrate some interesting figures. First slide one hexagon over another, so that the hole becomes pentagonal. Sliding two over two produces a square hole; three over three, triangular. If a number of such rings are cut out and made up permanently by gumming the folds, three of the Archimedean solids may be worked up in an effective manner. Twelve of the rings with pentagonal holes may be stuck together (with overlapping hexagons) to make

a sturdy model of the truncated icosahedron; sufficiently illustrative although the pentagonal faces are lacking. Similarly, a truncated octahedron (fig. 1) may be constructed from six of the rings with square holes; in fact, two such rings will suffice if they are connected by extra flaps of adhesive strips instead of overlapping hexagons. Again, the truncated tetrahedron may be constructed from two of the rings with triangular holes, or from one such ring attached by flaps to one extra hexagon.

FIG. 1.—PAPER MODEL OF TRUNCATED OCTAHEDRON

A large number of identical models of the truncated octahedron or of the truncated tetrahedron may be fitted together like bricks to fill any volume of space (with small tetrahedral cavities in the latter case). The hexagons are then the faces of a regular sponge or skew polyhedron, each vertex being surrounded by four hexagons in the former case, six in the latter. (See the *Proceedings of the London Mathematical Society* [2], 43:33-62 [1937], or *Scripta Mathematica*, 6:240-244 [1939].)

There are altogether three such regular skew polyhedrons. The third has square faces, six at each vertex, and may be built up from repetitions of a simple ring of four squares, like a cube with two opposite faces omitted. This last model has the peculiar property of being collapsible. It may be rendered rigid by inserting diagonal struts into two or more of the rings. These sponges have equal regular faces and equal angles, just like the five Platonic solids.

Another kind of generalized regular polyhedron is obtained by stellating those three of the Platonic solids that have obtuse dihedral angles; i.e., extending or producing the faces until they meet again in new vertexes, always preserving the rotational symmetry of the original solid. In this manner the octahedron leads to the *stella octangula* of Johannes Kepler (1619), which may be regarded as a compound of two interpenetrating tetrahedrons with edges that are the diagonals of the faces of a cube. A dodecahedron (fig. 2)

FIG. 2.—REGULAR DODECAHEDRON

leads to three of the four Kepler-Poinsot polyhedrons, as follows. The 12 faces of the small stellated dodecahedron are pentagrams or star pentagons (angle 36°) obtained by extending the sides of the ordinary pentagon until they meet again. The 12 faces of the great dodecahedron are larger pentagons having the same vertices as these pentagrams. The 12 faces of the great stellated dodecahedron are pentagrams obtained by extending the sides of the large pentagons. In other

words, the small stellated dodecahedron may be constructed by placing a pentagonal pyramid (with face angles of 36° at the apex) on each face of the ordinary dodecahedron; and the great stellated dodecahedron, by placing a triangular pyramid (again with angles of 36° at the apex) on each face of the icosahedron. The great dodecahedron may be derived from a solid icosahedron (of wood or wax, for example) by digging a shallow pyramidal pit in each face, and retaining the original edges. Finally, by stellating the icosahedron one can obtain the great icosahedron, as well as several compounds and many irregular but beautiful figures.

Material for Models.—It is not the purpose of mathematical models to prove propositions, but to aid understanding and to suggest further lines of investigation. They need not attain the standard of accuracy required for graphs or nomograms (*see* NOMOGRAPHY). But they should be constructed with reasonable care, and of suitable materials.

The nearest approach to a mathematically plane surface that occurs in nature is a face of a good crystal. In practice, thin sheet metal or cardboard suffices for many purposes although in certain cases transparent plastic or glass is to be preferred; in other cases, strings, or elastic, silk or cotton cords—which may be of different colours—arranged closely together and parallel, may be employed.

Descriptive Geometry.—For the study of such topics as descriptive geometry and perspective (*qq.v.*), a useful device is found in a pair of planes hinged together and possibly provided with a third plane of reference. Such folding planes, if perforated, are helpful in clarifying orthogonal projection. The models introduced by O. Reynolds and G. Cussons (1876) (fig. 3, left) and the later developments by A. H. Miller (fig. 3, centre) are interesting examples of this class. In the former type the problems are permanently drawn out, in the latter they may be built up before the eyes of the student (precaution being taken in the design to avoid distracting the student's attention from the mathematics to the mechanism), thus allowing the solution of the problems to be demonstrated in proper sequence step by step. In this class may be included the design (fig. 3, right) of H. G. Green described in the *Mathematical Gazette*, no. 174, as "A Model for Figures in Three Dimensions," which is particularly useful for three-dimensional and trigonometric studies. Posts may readily be fixed in the holes of the double base of the apparatus; and cords as lines of vision, serve

to illustrate questions of the man-and-flagstaff type, subtended angles, and so on.

Wooden Models.—Solid models of wood may be cut in sections to clarify many problems. An impressive example is shown in fig. 4, where a cube is dissected into six equal tetrahedrons without making any new corners. Three of the tetrahedrons are directly congruent; so are the other three, but they are the reflected images of the first three. All four faces of each tetrahedron are right triangles.

A further example is the well-known model of the binomial cube; *i.e.*, a cube built up of small cubes and prisms with edge lengths represented by arbitrary values of a and b , and an entirely new and larger cube $(a+b)^3$ being formable by a combination of blocks equalling $a^3 + 3a^2b + 3ab^2 + b^3$. The study of conic sections

FIG. 5.—CONE WITH INSCRIBED SPHERES AND SECTION PLANE

(*see* CONIC SECTION), so frequently treated analytically, is much simplified by the use of a model, such as the right circular cone, in which plane sections are made: (1) parallel to the base; (2) parallel to just one generating line of the cone; (3) inclined to the axis at an angle greater than the semivertical angle of the cone; and (4) inclined to the axis at an angle less than the semivertical angle of the cone. These give respectively the circle, parabola, ellipse and hyperbola (one branch), while a combination solid, wire and plane model allows demonstration (as in fig. 5) of the theorem that the inscribed spheres touch the plane of section at the two foci of the ellipse.

Problems concerned with interpenetration (*e.g.*, of a torus and a cylinder) can best be illustrated in wood since the intersection is produced in the course of manufacture and its shape may be separately examined (*see* fig. 6).

Technical Construction.—Symmetrical solids and surfaces of revolution can be turned in a lathe, a template representing a plane section through the axis being applied to the work from time to time until the whole solid of revolution is worked up. Surfaces that are not symmetrical around the axis may also be formed in a suitable lathe having a chuck that can produce eccentric motion.

FIG. 6.—TORUS AND CYLINDER

Such models may attain a high order of accuracy since micrometer measurements may be applied to the work in the machine. It is easy to represent many surfaces by means of fixed wires shaped and assembled to represent various sections (*see* fig. 7), but a more intriguing series of flexible models can be made up of rods or strips, pin-jointed or hinged at their extremities, since these provide a mechanism whereby ruled hyperboloids may be continuously converted into their confocal surfaces (fig. 7, bottom right).

FIG. 7.—CLASSROOM MODELS

FIG. 7.—WIRE MODELS: (TOP LEFT) ELLIPSOIDS; (TOP RIGHT) ELLIPTIC AND HYPERBOLIC PARABOLOIDS; (BOTTOM LEFT) TWO-SHEET AND ONE-SHEET HYPERBOLOIDS; (BOTTOM RIGHT, A) MOVABLE ROD MODEL OF ONE-SHEET HYPERBOLOID, (B) MODEL VIEWED FROM ABOVE

Thread Models.—Ruled surfaces (*i.e.*, surfaces generated by the motion of a straight line) fall naturally into a class for easy modeling, since the generators can be represented by successive stretched threads (*see* SURFACES). Thread models can, therefore, illustrate a wide variety of combinations as in fig. 8, which shows two circular disks drilled with equidistant holes close together, supported as shown and threaded with weighted cords so that the cords may slide through the lower holes. This model is a demonstration of a cylinder, when the disks and cords hang freely; a hyperboloid of revolution, when one or the other disk is rotated slightly relative to the other; and the limiting position of a double cone.

Threads stretched as generators across the bars of a jointed quadrilateral of which the sides are movable in pairs may be used to illustrate the changes from a plane, through all forms of hyperbolic paraboloid, to double plane. Figure 9 shows a model that comprises two bars pierced with equidistant holes, one bar being fixed, the other free to swing around an axis that can also be inclined at different angles to the fixed bar. It should be observed that the hyperbolic paraboloid cannot be made by simply twisting a plane sheet of metal. Surfaces that can be so developed from a plane (*e.g.*, cylinders and cones) are said to be developable.

Space Curves.—Such twisted curves may be modeled either by threads representing their tangents, as in fig. 10 (top left), or by wires suitably bent (top right). The tangents generate a surface which is also the envelope of the osculating planes.

FIG. 9.—BAR AND THREAD MODEL

board circles of regularly varying diameters set evenly apart in parallel vertical planes, whereby it is possible to evolve the whole family of quadric surfaces (*e.g.*, ellipsoids, hyperboloids, paraboloids).

A further advantage of this type of model is that the sections may be interlocked across an axis and thereby deformed at will, a feature which appears another way in the deformable circles of fig. 12 (bottom). In this type a number of different-sized wire circles are loosely jointed together across a diameter by a special form of hinge (Wiener's limited joint).

FIG. 10.—SPACE CURVES: (TOP LEFT) THE OSCULATING DEVELOPABLE OF A CUBIC ELLIPSE; (TOP RIGHT) THE HOROPTER, A SYMMETRICAL CUBIC ELLIPSE LYING ON A CIRCULAR CYLINDER; (BOTTOM LEFT) DUAL FIGURE; (BOTTOM RIGHT) EQUIPOTENTIAL LINES

Any twisted cubic (*i.e.*, curve of the third order) may be constructed as the residual intersection of two quadric cones that have a common generator. Figure 10 (bottom left) shows the dual figure: the envelope of planes touching two conics that have a common tangent line.

Figure 10 (bottom right) shows a physical application of twisted curves, illustrating the equipotential lines and lines of force corresponding to two electric conductors bearing equal charges.

Helical Surfaces.—Helicoids may best be demonstrated by either shaped wires or flat pieces of tin plate hinged together, the former providing the cheaper but less flexible medium. Typical examples are seen in fig. 11 (left), where the wires form helices lying on the surface, and (right) where the model is composed of small hinged sections.

Cardboard Models.—Figure 12 (top) shows several models made of thin sheets; *e.g.*, cardboard circles of regularly varying diameters set evenly apart in parallel vertical planes, whereby it is possible to evolve the whole family of quadric surfaces (*e.g.*, ellipsoids, hyperboloids, paraboloids).

A further advantage of this type of model is that the sections may be interlocked across an axis and thereby deformed at will, a feature which appears another way in the deformable circles of fig. 12 (bottom). In this type a number of different-sized wire circles are loosely jointed together across a diameter by a special form of hinge (Wiener's limited joint).

FIG. 11.—(LEFT) HELICES LYING ON A HELICOID; (RIGHT) POLYHEDRONS APPLIED TO THE THEORY OF THE BENDING OF SURFACES

The figures show the limiting positions of circle and sphere and the formation of prolate and oblate spheroids. Similar models may be readily made to illustrate the elliptic paraboloid and the hyperboloid of two sheets.

Surface Models.—The method of representing quadric surfaces by thin sheet circles arranged in parallel planes suggests the means of producing what is probably the most generally useful of all types: surface models of wood, clay or plaster, evolved by applying templates after the manner employed in shaping a model ship's hull. Such a model may represent a three-dimensional "graph," exhibiting the relations among such physical functions as the pressure, volume and temperature of a gas, as in the case of J. Thompson's model of 1871, made to illustrate the data obtained by Thomas Andrews in his classic experiments on a constant mass of carbon dioxide. A later application of the method was made by James Clerk Maxwell who, as the outcome of a suggestion by Josiah Willard Gibbs, used the quantities volume, energy and entropy in making his famous thermodynamic surface model in which the properties of a substance in its solid, liquid and gaseous states are

FIG. 12.—(TOP) CARDBOARD MODELS OF SECOND-ORDER SURFACES; (BOTTOM, LEFT AND RIGHT) FLEXIBLE WIRE CIRCLES

indicated by the geometrical properties of the surface. Maxwell showed how isothermal and isopiestic lines could be drawn upon it and that there is one position of the tangent plane in which it touches the surface in three points that represent the solid, liquid and gaseous states of the substance when the temperature and pressure are such that the three states can exist together.

Plaster Models.—Plaster casts can obviously be produced at less cost than the original mold; wherever feasible the method affords a convenient means of reproducing models of surfaces of revolution or of polyhedrons.

The surface of revolution is typically represented by the model in fig. 13 (left) (the surface of rotation of the tractrix about its

FIG. 13.—PLASTER MODELS OF (LEFT) TRACTROID; (RIGHT, FROM LEFT TO RIGHT) UNDULOID; NODOID; RING OF NODOID ARISING BY ROTATION OF THE LOOP; AND CATENOID, A MINIMAL SURFACE

asymptote) upon which may easily be marked, after molding, some samples of asymptotic lines, geodesics, etc. Some surfaces of constant mean curvature are shown in fig. 13 (right).

Surfaces of rotation having a constant negative Gaussian curvature are shown in fig. 14 (left), the pointed model being of the cone type and bearing geodesics and asymptotic lines, the other illustrat-

FIG. 14.—(LEFT) SURFACES OF ROTATION; (RIGHT) CUBIC SURFACE

ing the hyperboloid type and being marked with geodesics and geodesic circles. Figure 14 (right) illustrates a cubic surface having four real conical nodes. A form of Kummer surface (singularity surface of a quadratic complex of lines) is shown in fig. 15. It is of the fourth order, of the fourth class, and has 16 real nodes and the same number of singular tangent planes, each touching the surface all along a conic. A further example of a surface of the fourth order is Steiner's Roman surface, shown in fig. 16. It has the equation $y^2z^2 + z^2x^2 + x^2y^2 + xyz = 0$, crosses itself along each of the co-ordinate axes and is one-sided. Its asymptotic lines are indicated on the model.

An interesting example of a model illustrating a minimal surface is shown in fig. 17 (left). It contains a system of real parabolas, the planes of which make a constant angle with a fixed plane. Figure 17 (right) is a representation of winding points of the first and second order on Riemann

FIG. 15.—KUMMER SURFACE

surfaces. They arise, for instance, when the complex functions z^t and \bar{z}^t are considered in the neighbourhood of the origin.

Linkages and Kinematical Models.—Linkages (*q.v.*) may be described as systems of bars connected by pin joints or hinges to allow deformation without sliding motion (*see* fig. 18). The most famous plane linkage is C. N. Peaucellier's invensor with six bars that consist of a rhombus APBQ and two equal links joining the opposite vertices A and B to a fixed point O. When P is constrained to trace a given curve, Q will trace the inverse curve. In particular, if P is joined by a seventh link to a fixed point M that has a distance from O equal to the length of this new link (so that P traces a circle through O), then Q will trace a straight line.

FIG. 16.—STEINER'S ROMAN SURFACE

FIG. 17.—(LEFT) MINIMAL SURFACE MODEL; (RIGHT) RIEMANN SURFACES

Space linkages may be made of rigid flat plates hinged together. In the special case when the hinges are all parallel, such a space linkage is clearly equivalent to a plane linkage. Peaucellier's invensor was preceded by the remarkable space linkage of P. F. Sarrus (1853), also shown in fig. 18. This consists of six plates, p, a, b, q, d, c , having three parallel hinges at the edges pa, ab and

FIG. 18.—(LEFT) PEAUCELLIER'S PLANE LINKAGE; (RIGHT) SARRUS' SPACE LINKAGE

bq and three parallel hinges at the edges pc, cd and dq . The plates p and q will remain parallel; if the former is fixed, every point of the latter will describe a straight line.

MATHEMATICAL SYMBOLS constitute a language in which quantities, operations with them, and their relations to each other are represented in abstract terms, clearly and concisely. As records, symbols eliminate much needless remembering, and the

statements themselves frequently suggest procedures to be followed in mathematical thinking.

The symbols used in the earliest printed works in arithmetic and algebra (*qq.v.*) were abbreviations and initial letters such as the hand copyists of earlier days had used. These short cuts were later supplemented by signs devised for specific purposes. This was the case in the first known use of the equality sign ($=$) which Robert Recorde introduced in his algebra (1557) with the explanation: "... to avoide the tedious repetition of these woordes: is equalle to: I will sette as I doe often in woorkes use, a paire of paraleles, or Gemowe (*i.e.*, twin) lines of one lengthe, thus: $==$, because noe .2. thynges, can be moare equalle."

From the 15th to the 17th centuries there was great activity in representing unknown quantities and their powers and in indicating operations with numbers. For relationships among numbers, the symbols $<$, $=$, and $>$ (meaning less than, equal to, and greater than) sufficed. Various symbols were proposed for the same idea; in the hands of several authors, a single symbol might have as many different meanings. Some symbols seem to have survived because of the importance of the people who introduced them; others apparently persisted because they were adapted to new developments in subject matter. The result is that the symbols of elementary mathematics have been aptly described by F. Cajori as "a mosaic of individual signs of rejected systems."

Among 16th–17th-century mathematicians who gave serious study to the subject of mathematical symbols were François Vieta, William Oughtred, René Descartes and Gottfried Wilhelm Leibniz (*qq.v.*). Vieta used vowels for unknown quantities and consonants for known quantities. This made possible the representation of an equation in general terms. Descartes followed this pattern but used the letters from the beginning of the alphabet as knowns and those from the end of the alphabet as the unknowns. Oughtred experimented with more than 150 symbols, of which only a few survive. Toward the close of the 17th century, Leibniz made a careful study of the symbols then in use with particular attention to their clarity and to the ease with which they could be printed. It was in the course of this work that Recorde's equality sign came to be preferred to its competitors.

The use of symbols had its detractors in this period; according to the philosopher Thomas Hobbes (*q.v.*), "Symbols are poor unhandsome though necessary scaffolds of demonstration." In reference to John Wallis' work, Hobbes wrote, "And for . . . your Conic Sections, it is so covered over with the scab of symbols, that I had not the patience to examine whether it be well or ill demonstrated."

The differing approaches to the calculus held by Sir Isaac Newton (*q.v.*) and Leibniz produced different notations. For more than a century, British mathematicians clung to Newton's symbols, mathematicians on the continent to those of Leibniz (*see* CALCULUS, DIFFERENTIAL AND INTEGRAL).

In the 18th century, Leonhard Euler (*q.v.*) contributed an unusual number of symbols that lasted in mathematics; few men have been responsible for more than one. Among Euler's symbols are $f(x)$, meaning a function of x ; e , the base of the natural logarithms; Σ , indicating summation; and i , standing for $\sqrt{-1}$.

As a young man Leibniz had a dream of devising a method of representing ideas in a symbolic language. He failed to implement this and the project lay dormant until the 19th century. Then, following the publication of George Boole's *Analysis of Logic* (1847), the attention of mathematicians began to be directed toward the matter of symbolic logic. And in the first half of the 20th century, the study of the structure of mathematics became of prime importance. Each of these activities was accompanied by specific symbolism. Thus the modern symbolism for sets, groups (*q.v.*) and the other materials of the newer algebra, and the symbols for symbolic logic exhibit a variety similar to that which accompanied the development of algebra and of the calculus (*see* SET THEORY [THEORY OF AGGREGATES]).

The precision of these symbols is striking. In the matter of sets, the statement $R = \{x|x > 2\}$ means that R is the set of values x such that x is greater than 2. If A and B are two sets, then $A \cap B = \{x|x \text{ belongs to } A \text{ and } x \text{ belongs to } B\}$; *i.e.*, the intersec-

tion of A and B means the set of values of x that belong to both A and B . The symbol ϕ signifies an empty set.

In logic (*q.v.*), if p and q are propositions or statements, then $p \equiv q$ means p or q but not both; $p \vee q$ means p or q or both; and $p|q$ means not both p and q . New symbols are extensions of the old; for example, if A and B are two points, then \widehat{AB} represents the line segment that joins them; \widehat{AB} is the length of the arc between them if A and B lie on a circle. The symbol \overrightarrow{AB} has been chosen to represent a vector (see VECTOR ANALYSIS). What Newton called the "Analytick Language" has become more precise and more flexible.

MATHEMATICAL TABLES. By a mathematical table is meant any set of tabulated values the primary purpose of which is to render less laborious the work of professional computers in mathematics, engineering, astronomy, physics, chemistry, statistics and other fields of applied science. The term mathematical tables as commonly employed includes specifically the values of mathematical functions such as $\log x$, $\sin x$, etc., and lists of special quantities such as prime numbers, mathematical constants, etc. In a broad sense it is sometimes used to include certain numerical values obtained empirically in scientific laboratories. In this category, for example, are actuarial tables, lists of physical constants, astronomical tables, etc.

Classification.—The need for some system of classification of tables was early recognized, and such a system was made by Arthur Cayley (1821–95) to accompany the extensive report by James W. L. Glaisher on *Mathematical Tables* published by the British Association for the Advancement of Science in 1873. Modern development of the field revealed the inadequacy of this classification, and a system was devised in 1940 by the Committee on Mathematical Tables and Other Aids to Computation of the National Research Committee of the United States as follows:

- A. Arithmetical tables; mathematical constants
- B. Powers
- C. Logarithms
- D. Circular functions
- E. Hyperbolic and exponential functions
- F. Theory of numbers
- G. Higher algebra
- H. Numerical solution of equations
- I. Finite differences
- J. Summation of series
- K. Statistics
- L. Higher mathematical functions
- M. Integrals
- N. Interest and investment
- O. Actuarial science
- P. Engineering
- Q. Astronomy
- R. Geodesy
- S. Physics
- T. Chemistry
- U. Navigation
- V. Calculating machines and mechanical computation

Basic Concepts.—Most mathematical tables are designed to give the numerical values of some particular function $f(x)$ corresponding to a set of values of the independent variable x . Thus tables of square roots provide values of the function \sqrt{x} over a range of values of x , let us say from 1 to 10,000. The numbers recorded in the table are called tabular entries, and the values by which the table is entered, namely the values of x , are called the arguments. Such an array of values is called a single-entry table. Although such tables are the most common type, functions of two variables $f(x, y)$ are frequently tabulated. Thus, multiplication tables record the values of the product xy in terms of the two arguments x and y . Such arrays of values are called double-entry tables.

The length and the size of tables depend upon the character of the functions tabulated, the order of the approximation desired and the uses for which the tables are designed. For ex-

ample, in tabulating $\sin x$, where x is given in degrees, minutes and seconds, it is sufficient to take x by appropriate intervals from 0° to 90° , since the numerical values repeat from quadrant to quadrant. But if x is given in radian measure, then, because of the incommensurability of π , a complete table would require that x be taken from 0 to infinity. Tables have actually been constructed to 100 radians. The interval over which the values of the argument are taken is called the range of the table, and the interval between the argument entries is called the tabular interval. The number of decimal places to which the function is computed is called the place value of the table. Thus we speak of a table of logarithms computed to five decimal places as a five-place table, or a table computed to n decimal places as an n -place table. Sometimes, however, it is more important to refer to the number of significant figures rather than to the decimal places. For example, 22022.466 is an approximation to three decimal places although it contains eight significant figures. Tables which emphasize significant figures are often referred to as n -figure tables. The size of a table clearly depends upon three factors; namely, the range, the tabular interval and the place value. For much practical work, tables computed to four or five decimal places are usually sufficient and many important collections are computed to this approximation. However, other needs have required more place values for certain functions.

A table is said to be linear if the tabular interval is chosen small enough so that linear interpolation is sufficient to obtain, to the place-value approximation of the table, the values of the function at unrecorded value of the argument. For example, a five-place table of the function $\log \sin x$ is linear, except near 0° , if the tabular interval is one minute, but a seven-place table is computed at intervals of ten seconds. Aside from its convenience, a linear table has the advantage of serving also as a table of the function inverse to the one tabulated. Thus a linear table of logarithms is also a table of antilogarithms, for if one enters the tabular values with a number he may obtain, by inverse interpolation, the corresponding argument. This value is the antilogarithm of the number. Similarly a linear table of $\sin x$ will also provide the values of $\arcsin x$, and a linear table of squares may be used to compute square roots.

When values of a function are needed over a long range, it is often impossible to choose the tabular interval sufficiently small to attain linear interpolation without making the table too large. (See INTERPOLATION AND EXTRAPOLATION.) In this case differences of second and higher order may be provided for interpolation. Various types of differences have been given, the most usual, particularly in older tables, being the ordinary differences, Δ , Δ^2 , etc., which enter into the Newton-Gregory interpolation formula:

$$f(x + ph) = f(x) + p\Delta f + \frac{1}{2}p(p-1)\Delta^2 f + \dots$$

where h is the tabular interval, x any argument, and p a fraction.

Many recent tables have provided central differences, δ^2 , δ^4 , etc., instead of ordinary differences, since the Everett formula for interpolation is specially adapted to their use. A few tables have printed derivatives instead of differences, in which case the interpolation formula has the convenient form:

$$f(x + ph) = f(x) + phf'(x) + \frac{1}{2}p^2h^2f''(x) + \dots$$

where, as above, h is the tabular interval, x any argument, and p a fraction.

Inverse interpolation in tables which require differences of second or higher order for direct interpolation is usually difficult. Hence such tables are not useful as tables of the functions inverse to those tabulated. For this reason, if the tabular interval is not chosen sufficiently small to permit linear interpolation, two tables are required to evaluate any function whose inverse is also desired. Thus one finds tables of sines and tables of inverse sines, tables of logarithms and tables of antilogarithms, tables of elliptic functions and tables of elliptic integrals, etc.

As to the value of a table the following is a quote from Glaisher:

The intrinsic value of a table may be estimated by the actual amount of time saved by consulting it; for example, a table of square roots

to ten decimals is more valuable than a table of squares, as the extraction of the root would occupy more time than the multiplication of the number by itself. The value of a table does not depend upon the difficulty of calculating it; for, once made, it is made forever and as far as the user is concerned the amount of labour devoted to its original construction is immaterial. In some tables the labour required in the construction is the same as if all the tabular results had been calculated separately; but in the majority of instances a table can be formed by expeditious methods which are inapplicable to the calculation of an individual result. This is the case with tables of a continuous quantity, which may frequently be constructed by differences. The most striking instance perhaps is afforded by a factor table or a table of primes; for, if it is required to determine whether a given number is prime or not, the only universally available method (in the absence of tables) is to divide it by every prime less than its square root or until one is found that divides it without remainder. But to form a table of prime numbers the process is theoretically simple and rapid, for we have only to range all numbers in a line and strike out every second number beginning from 2, every third beginning from 3, and so on, those that remain being primes. Even when the tabular results are constructed separately, the method of differences or other methods connecting together different tabular results may afford valuable verifications. By having recourse to tables not only does the computer save time and labour, but he also obtains the certainty of accuracy.

Notation.—In describing the range, the tabular interval and the place value of tables, a notation has recently come into general use. It may be best described by an example. Thus, let us suppose that we are describing H. Andoyer's table of $\sin x$ which has been computed to 15 decimal places over a range from 0° to 90° at intervals of $10''$. All these facts are contained in the simple statement that the values of $\sin x$ are given for $x = [0^\circ (10'') 90^\circ; 15D]$. More complicated ranges may be similarly expressed. Thus, a recent table of e^x gave 15 decimal values from $x = 1$ to $x = 2.5$ at intervals of .0001 and from 2.5 to 5 at intervals of .001. We might then write that the function was tabulated for $x = [1 (.0001) 2.5 (.001) 5; 15D]$. If the approximation was to significant figures rather than to decimal places, then S is substituted for D . Thus, the table just described also gave the values of the function from $x = -100$ to $x = +100$, at intervals of 1, to 19 significant figures. These facts are included in the statement that the function was evaluated for $x = [-100 (1) +100; 19S]$.

The Computation of Tables.—The computation of tables is an art to which great mathematical ingenuity has been devoted in the 20 or more centuries during which tables have been made. A broad knowledge of the theory of functions and the calculus of finite differences is a primary requirement for anyone beginning an extensive computing program, since many hours of computing labour can be saved by the use of special properties of functions or by the appropriate adaptation of some of the formulas in the difference calculus.

The first task of the computer is to determine (1) the range over which the function is to be evaluated, (2) the approximation to be attained and (3) the tabular interval. The determination of the first two depends primarily upon the purposes for which the table is to be used; the last upon the order of interpolation contemplated. If the table is to be linear, that is to say, if linear interpolation is to be used, then the tabular interval depends upon the degree of the approximation. As an example, let us consider the function $\log \sin x$, where x is in degrees. Standard seven-place tables usually give this function for $x = 0^\circ (1'') 6^\circ (10'') 84^\circ (1'') 90^\circ$. Linear interpolation to seven places is attained throughout this table, except very close to 0° ; but this would not be the case for, let us say, a tabular interval of $1'$, which is the one used in five-place tables of the same function. In most cases the tabular interval may be estimated from the equation $|\Delta^2 f(x)| = h^2 |D^2 f(x)|$, where h is the tabular interval, $|\Delta^2 f(x)|$ is the absolute value of the second difference of the function at argument x , and $|D^2 f(x)|$ is the absolute value of the second derivative. In order to attain seven-place accuracy by linear interpolation, it is clear that $|\Delta^2 f(x)|$ cannot be greater than 10^{-8} . Hence the upper limit of h^2 (in radian measure) is approximately equal to $10^{-8}/|D^2 f(x)|$. Computing the second derivative of $\log \sin x$, we obtain $|D^2 f(x)| = \csc^2 x/M$, where $M = .43429$. Hence we have $h^2 = 10^{-8} M \sin^2 x$, or $h = \sqrt{M} 10^{-4} \sin x = 6.590 \times 10^{-5} \sin x$. For $x = 6^\circ$ we find that $\sin x = .1045$, and thus we obtain

the tabular interval $h = 6.887 \times 10^{-6}$ radians $= 14''$. From this it may be concluded that, from $x = 6^\circ$ to the end of the table, linear interpolation is assured to seven-place accuracy if the interval is at least as small as $14''$. The choice of $10''$ is thus below the required value and was made for convenience of those using the table.

After the determination of the tabular interval, the computer faces the task of evaluating the function over the range of values which he has selected. In modern times the powerful tools of mathematical analysis have been at his disposal; many types of expansions exist for his use. This was not the case in earlier times. For example, Claudius Ptolemy (c. A.D. 150) in computing his table of chords, which is described in more detail below, required the most ingenious theorems of the ancients to attain a six-place approximation. Thus Ptolemy found it necessary, in evaluating his critical quantity: chord $1^\circ = 2 \sin \frac{1}{2}^\circ$, to establish with much effort the inequality: $\frac{2}{3}$ chord $1\frac{1}{2}^\circ < \text{chord } 1^\circ < \frac{4}{3}$ chord $\frac{1}{2}^\circ$. Computing by a succession of square roots the upper and lower limits of the inequality, Ptolemy obtained a value for chord 1° which was correct to six places. The computer today, however, has available the power series

$$\sin x = x - \frac{x^3}{3!} + \frac{x^5}{5!} - \frac{x^7}{7!} + \dots$$

by which approximations to ten or more places are readily achieved.

In addition to power series, the modern table maker has available to his use asymptotic series, continued fractions, iterative processes, expansions in orthogonal functions, inverse factorial series and other types of series. He has certain devices by means of which the rapidity of the convergence of his series may be increased. Moreover, he has at his disposal the various formulas of the calculus of finite differences, which are adapted to interpolation, numerical integration, differentiation, etc.

In constructing a table of values of a function the usual method of procedure is to compute first a set of key values over some convenient set of coarsely spaced values within the range. These key quantities are computed to more places than are to be retained in the final table. The function is then computed at the intervening values of the argument by what is called subtabulation. This may be accomplished by means of ordinary interpolation, but when many values are desired, as in the case of extensive tables, the differences of the functions at the tabular interval may be computed from the differences of the key values and these in turn used to construct the tabular values.

In the computation of tables which have an extensive range it is often useful to employ certain fundamental properties of the functions tabulated. For example, from a table of values of the gamma function $\Gamma(x)$, computed between $x = 1$ and $x = 2$, an extension of the table is readily computed between $x = 2$ and $x = 3$ by making use of the well-known difference relationship: $\Gamma(x+1) = x\Gamma(x)$. Thus $\Gamma(2.5)$ is obtained from $\Gamma(1.5)$ merely by multiplying the latter value by 1.5. It is clear that the table can be extended to any value by successive applications of this process. Similarly tables of e^x are extended by observing that $e^x \times e^y = e^{x+y}$. In the absence of convenient properties of the kind given above, a function may be evaluated over an extensive range by a proper application of the series

$$f(x+h) = f(x) + hf'(x) + \frac{1}{2}h^2f''(x) + \dots$$

Thus, let us suppose that a function has been tabulated to some value of the argument x , and that by means of differences or otherwise the values of the derivatives $f'(x)$, $f''(x)$, etc., have also been computed at x . It is clear that the table can then be extended to $x+1$ by letting h range over the values from 0 to 1. Once the function and its derivatives have been evaluated at $x+1$, the formula is shifted to this new argument and the computation of the table continued. This device has been used effectively in the formation of tables of the Bessel functions $J_0(x)$ and $J_1(x)$ over a long range.

As an example of an iterative process we may cite what has been called Hero's formula for the extraction of square roots. If N is the number whose square root is desired, and if x_1 is

some approximation to the root, then a better approximation will be given by the formula: $x_2 = \frac{1}{2}(N/x_1 + x_1)$. Higher approximations are obtained by successive repetitions of the formula. This device is very effective in extending existing tables of square roots to additional place values, since one iteration is usually sufficient to double the order of the approximation.

Prodigies of computation have been achieved by means of some of these modern devices. For example, William Shanks (1812-1882) in 1873 published a value of π to 707 places (of which only 527 are believed to be correct), using Machin's formula:

$$\frac{1}{4}\pi = 4 \arctan \frac{1}{5} - \arctan \frac{1}{239}$$

The values of the inverse tangents were found from the ordinary power-series expansion of the function. An approximation for e , the base of natural logarithms, to 707 decimal places was published in 1926 by D. H. Lehmer who used continued fractions. Such extreme values have no intrinsic merit, for one may show that if the radius of space is assumed to be of the order of 2.7×10^{10} parsecs (1 parsec = 3.258 light years) and if the diameter of an electron is assumed to be of the order of 2×10^{-13} centimetres, then a value of π to 41 decimal places is sufficient to express the circumference of space in electron-diameters.

The next task of the computer, and perhaps his most important one, is to assure the accuracy of his table. The difficulty of attaining complete accuracy may be indicated by the fact that one error was detected in the 82nd edition of a well-known standard table, which had been issued continuously for more than a century. The accuracy of a table is sometimes checked by an independent recomputation of the values, preferably by a method different from that used in the original work; but more commonly the computer differences his tabular values. A common error in some tables is the inaccuracy of the last decimal place of the approximation, since this figure is obtained by rounding off the last place in the computed values.

The difficulty in the situation is illustrated by the fact that a five-place table of logarithms cannot be formed completely from a seven-place table of logarithms. For example, in a seven-place table of $\log x$ one finds for $x = 3012$ the tabular entry 4788550. In forming a five-place table should this be reduced to 47885 or increased to 47886? The answer is obviously contained in the question whether the last two figures in the seven-place table were rounded off from a number less than 50 or greater than 50. Consulting a ten-place table we find that the corresponding logarithm is 4788549675 and thus the logarithm in a five-place table should appear as 47885. It is often a matter of considerable difficulty to answer a question of this kind.

The History of Tables.—Mathematical tables appear in the earliest records of history. Thus, certain elementary numerical values connected with the combination of the unit-numerator fractions of the Egyptians are found in the Rhind mathematical papyrus, the copy of a scribe named Ahmes, written some time before 1700 B.C. More extensive than these are the records of the Babylonians, dated perhaps as early as 2000 B.C., which contain multiplication tables and tables of reciprocal values, useful in performing elementary arithmetical operations.

The first mathematical table in the modern sense of the word is the table of chords found in the *Syntaxis Mathematica*, or as it is more commonly called, the *Almagest* of Claudius Ptolemy. This remarkable table, dating from the middle of the 2nd century A.D., gives the values of the chords of a circle at intervals of one-half degree to six-place approximation. In the computation of this table, Greek mathematical ingenuity reaches one of its highest points. It is probable that the table is derived from an earlier work by Hipparchus (c. 150 B.C.), which is mentioned by Theon of Alexandria. Three lines of this table as it appears in a Greek edition of the *Almagest* published in Basel in 1538, together with a translation into modern symbols, is given below:

KANONION

Translation of the CANON

$\kappa\gamma$	$\kappa\gamma$	$\pi\epsilon$	$\kappa\zeta$	\circ	α	α	$\lambda\gamma$	23	23	55	27	0	1	1	33
$\kappa\gamma\zeta$	$\kappa\delta$	$\kappa\zeta$	$\iota\gamma$	\circ	α	α	λ	23½	24	26	13	0	1	1	30
$\kappa\delta$	$\kappa\delta$	$\pi\zeta$	$\eta\eta$	\circ	α	α	$\kappa\zeta$	24	24	56	58	0	1	1	26

For the translation into Hindu-Arabic numerals the following table of equivalent symbols is necessary:

α	β	γ	δ	ϵ	ζ	η	θ	ι	κ	λ	μ	ν	ξ	\omicron	π	ρ	σ	
1	2	3	4	5	6	7	8	9	10	20	30	40	50	60	70	80	90	100

Fractions were customarily written with one accent on the numerator and two on the denominator, which was written twice. Thus we have: $\iota\gamma' \kappa\theta'' \kappa\theta'' = 13/29$. For fractions of unit numerator the denominator only was written. Thus we interpret $\mu\theta'' = 1/44$, $\gamma'' = \frac{1}{2}$, etc. Although the usual way of writing $\frac{1}{2}$ was β'' the symbol σ'' was also in common use for $\frac{1}{2}$ as we observe in the table of Ptolemy.

The modern character of this table is seen from the fact that it contains first the values of the argument, then the tabular entries and finally a table of differences. To interpret the table we need to know only that Ptolemy used the sexagesimal system of numbers. He divided the radius into 60 parts, each of these units into 60 parts, and so on. Hence, in terms of the radius, we have

$$\text{chord } 24^\circ = \frac{24}{60} + \frac{56}{60^2} + \frac{58}{60^3} = .415824$$

This value is equivalent to $\sin 12^\circ = \frac{1}{2} \text{ chord } 24^\circ = .207912$, which is correct to the last place.

Although mathematical tables were prepared and used both by Hindu and Arab mathematicians, it was not until the 15th century that modern development of this art began. Great tables of the natural trigonometric functions were started under the direction of Georg Purbach (1423-61), who divided the radius into 600,000 parts; and his pupil Johann Müller, more generally called Regiomontanus (1436-76), who computed a table of sines to every minute of arc with a radius of 1,000,000. In the first book of his *De revolutionibus orbium coelestium* (1543), Nicolaus Copernicus (1473-1543) gave a five-place table of sines. The first table of tangents appeared in the *Canon foecundus* (1553) of Erasmus Reinhold and the first table of secants in the contemporary *Tabula benefica* of Franciscus Maurolycus (1494-1575).

Among the greatest labours ever undertaken in table making were those of Rheticus, Otho and Pitiscus. George Joachim, generally known as Rheticus (1514-76), a student of Copernicus, began the task of computing a table of the trigonometric functions to 15 decimal places for every 10 seconds of arc and for every second in the first and last degrees of the quadrant. He completed the tables of sines and began the construction of tables of tangents and secants, but died before they were completed. It is said that he kept several calculators in his employ for 12 years.

The great task was finished by his pupil Valentine Otho (c. 1550-1605), who produced the celebrated ten-place canon *Opus palatinum* in 1596. The 15-place table of sines was published in 1613 under the title of *Thesaurus mathematicus* by Bartholomäus Pitiscus (1561-1613). These works are the basis of modern tables.

With the independent publication of a table of logarithms by John Napier (1550-1617) in Scotland in 1614 and a brief table of antilogarithms by Joost Bürgi (1552-1632) in Prague in 1620, numerical computation took a fresh start. Napier's table of logarithms extended to eight places, but his base was essentially $1/e$, $e = 2.7183$ Although it is common to refer to tables of logarithms to the base e , namely of $\log_e x$, as tables of Napierian logarithms, the more proper name is natural or hyperbolic logarithms. The first table of logarithms to the base 10 was computed by Henry Briggs (1561-1631) and published under the title *Arithmetica logarithmica* in 1624. The computations were made to 14 decimal places, but included only the logarithms of numbers from 1 to 20,000 and 90,000 to 101,000. Although Briggs had intended to complete his monumental computations he was anticipated in this by E. de Decker in his *Tweede Deel der Nieuwe Telkonst* (1627) and A. Vlacq (c. 1600-67) in his so-called *Editio secunda* of Briggs's *Arithmetica* (1628). These men, who were essentially partners in the undertaking, gave ten-place logarithms together with differences over the integers 1 to 100,000.

The work of De Decker and Vlacq was reprinted by G. Vega in 1794 under the title *Thesaurus logarithmorum completus*. Vega also included Vlacq's table of log sines and log tangents described

below and a table of natural logarithms to 48 places computed by J. Wolfram, a lieutenant of artillery in the Netherlands. Wolfram's tables, which extended over all the numbers up to 2,200 and all the primes, together with a few numbers whose least factor is a large prime, to 10,000, was printed for the first time in the *Sammlung* by J. C. Schulze (1778).

Tables of the logarithmic trigonometric functions followed shortly the publication of the logarithmic tables of integers. The fundamental contributions were made (1) by Vlacq in his *Trigonometria artificialis* (1633), which gave ten-place values of log sines and log tangents to every 10 seconds of the quadrant with differences, and (2) by Briggs in his *Trigonometria Britannica* (1633), which gave the natural sines to 15 places, tangents and secants to 10 places, log sines to 14 places and log tangents to 10 places at intervals of 0.01° from 0° to 45° . It is interesting to observe that mathematicians have followed Vlacq's division of the degree rather than that of Briggs. A new turn to this question was given at the time of the French Revolution, when weights and measures were being reduced to the metric system.

Gaspard Riche, baron de Prony (1755-1839), was placed in charge of a project to produce the values of the trigonometric functions in terms of centesimal units, namely divisions of the quadrant into 100 parts called grades, each grade into 100 minutes, and each minute into 100 seconds. This vast undertaking, called the *Tables du Cadastre* from the fact that Prony was the director of the Bureau du Cadastre, was carried out on a scale which involved the calculation of the natural sine to 22 decimal places and log sine and log tangent to 14 decimal places. Although the original work was never published, tables based upon it have appeared.

With the now rapidly growing demands both of science on the one hand and commerce on the other, as shown by extensive manuals of navigation, the number of tables increased rapidly. The 18th century produced more tables than the 17th; and the 19th, by greatly expanding the number of functions tabulated, increased both the volume of tables and their variety. During the first half of the 19th century, for example, we find the origin of tables of the elliptic integrals, the elliptic functions, the hyperbolic functions, the gamma function, the probability functions, the Bessel functions, and many others. With the widespread use of rapid calculating devices the 20th century has already increased by severalfold the total number of tables produced in preceding centuries. Hence the history of tables is becoming rather a history of the tables of special functions.

The Bibliography of Tables.—With the rapid increase in mathematical tables it became clear more than a century ago that if the needs of science, engineering and commerce were to be served properly, some systematic account of the origin, size and accuracy of tables must be made. A number of excellent historical and bibliographical surveys were produced during the 19th century by Glaisher for the British Association for the Advancement of Science, and by Augustus de Morgan, J. B. J. Delambre and Charles Hutton.

Such surveys were supplemented by a number of others, but by 1943 the need for current information became so great that the National Research Council of the United States established a special quarterly journal, *Mathematical Tables and Other Aids to Computation*, designed to provide reviews of recent tables, a record of manuscript tables, lists of errata in standard tables, miscellaneous notes on tabular material, publication of bibliographies of tables in special fields of research and of particular functions, as well as descriptions of calculating machines.

In addition to the report of Glaisher referred to above, others of value concerning tables of historical interest include the following: (1) De Morgan's article on "Table" in the *Penny Cyclopaedia* (1842) and *Supplement* (1846), which also appeared later with numerous additions in the *English Cyclopaedia*, Arts and Science section (1861); (2) Glaisher's articles on "Logarithms" and "Table, Mathematical" in the 11th ed. (1910-11) of the *Encyclopaedia Britannica*; Hutton in the first six editions of his *Mathematical Tables* (1785-1820).

Reports made on tables of special functions include the following: (1) J. Henderson's *Bibliotheca Tabularum Mathematicarum*,

part i; "Logarithms of Numbers" (1926); (2) D. H. Lehmer, *Guide to Tables in the Theory of Numbers* (1940); (3) Harry Bateman and R. C. Archibald, "A Guide to Tables of Bessel Functions," published as no. 7 (1944) of *Mathematical Tables and Other Aids to Computation*.

A remarkable work of A. Fletcher, J. C. P. Miller and L. Rosenhead, *An Index of Mathematical Tables*, 2nd ed. (1962), is a comprehensive guide to tables.

See also MATHEMATICAL INSTRUMENTS and the references given therein for electronic and mechanical computing methods.

BIBLIOGRAPHY.—In addition to the bibliographies mentioned above, the reader is referred to the following works: E. T. Whittaker and G. Robinson, *The Calculus of Observations* (1924 and 1937); J. B. Scarborough, *Numerical Mathematical Analysis* (1930); R. Mehmke, "Numerisches Rechnen," *Encyk. der Math. Wiss.* (1900-04); E. M. Horsburgh, *Modern Instruments of Calculation* (1914); L. J. Comrie, *Interpolation and Allied Tables* (1936); Karl Pearson, *On the Construction of Tables and on Interpolation*, Univariate Tables, Tracts for Computers, no. 2 (1920), Bivariate Tables, no. 3 (1920); J. K. Steffenson, *Interpolation* (1927); H. T. Davis, *Tables of the Higher Mathematical Functions*, vol. 1 (1933), vol. 2 (1935); Publications of the Mathematical Tables project; E. Jahnke and F. Emde, *Funktionentafeln* (1943); A. V. Lebedev and R. M. Fedorova, *Guide to Mathematical Tables* (1960); M. Warmus, *Tables of Elementary Functions* (1961); R. A. Fisher and F. Yates, *Statistical Tables for Biological, Agricultural and Medical Research*, 6th ed. (1963). (H. T. D.; X.)

MATHEMATICS (ARTICLES ON). An introductory perspective on mathematics as a creative force is offered by the article SCIENCE, HISTORY OF. In this general survey, mathematical discoveries are seen in the contexts of the sciences to which they contributed, and the reader who is unversed in mathematics can obtain at least a glimpse of its philosophy and its objectives.

Similar insights will be found in the introductory sections of various articles in the fields of physics and chemistry. For example, numerical relationships are seen as clues to the dynamics of nature in HARMONIC ANALYSIS, and to its architecture in such articles as ATOM and PERIODIC LAW. MATHEMATICS, HISTORY OF, outlines the evolution of the major branches of mathematics, and MATHEMATICS, FOUNDATIONS OF, describes their basic principles and methods.

To facilitate study, it is customary to divide mathematics into somewhat arbitrary subfields, but it will be apparent upon reading various of the articles that few subjects in modern mathematics can be thought of as lying wholly in any one of these so-called classical areas.

The first of these areas includes the more elementary phases that are discussed in such articles as ARITHMETIC; MENSURATION; NUMBER; and NUMERALS AND NUMERICAL SYSTEMS. The properties of whole numbers are treated in NUMBERS, THEORY OF, and those of imaginary numbers are discussed in COMPLEX NUMBERS.

ALGEBRA and ALGEBRA, HISTORY OF, outline the history and basic principles of this discipline. Specialized branches of algebra are treated in ALGEBRAS (LINEAR) and TENSOR ALGEBRA. Articles on topics related to algebra include BINOMIAL THEOREM; EQUATIONS, THEORY OF; FIELDS; GROUPS; GROUPS, CONTINUOUS; GROUPS, TRANSFORMATION; GROUPS AND ALGEBRAS, REPRESENTATIONS OF; and POLYNOMIAL.

GEOMETRY surveys the history and general principles of the branch of mathematics dealing with the properties of space, and is supplemented by such articles as CONIC SECTION; CURVES; CURVES, SPECIAL; MANIFOLDS; SOLIDS, GEOMETRIC; and SURFACES. Articles on special geometries include ALGEBRAIC GEOMETRY; ANALYTIC GEOMETRY; DESCRIPTIVE GEOMETRY; DIFFERENTIAL GEOMETRY; GEOMETRY, NON-EUCLIDEAN; PROJECTIVE GEOMETRY; RIEMANNIAN GEOMETRY; TOPOLOGY, ALGEBRAIC; and TOPOLOGY, GENERAL.

TRIGONOMETRY outlines the history and general principles of this branch of mathematics, in which techniques of geometry, algebra and arithmetic are applied.

The branch of analysis known as calculus is treated in CALCULUS, DIFFERENTIAL AND INTEGRAL. Specialized types of calculus are discussed in CALCULUS OF DIFFERENCES and CALCULUS OF VARIATIONS. Related articles include DIFFERENTIAL EQUATIONS, ORDINARY; DIFFERENTIAL EQUATIONS, PARTIAL; INTEGRATION AND MEASURE; and OPERATORS, THEORY OF. The theory of series,

which preceded calculus but was greatly advanced by its discovery, is treated in SERIES; FOURIER SERIES; INTERPOLATION AND EXTRAPOLATION; and NUMBER SEQUENCES.

ANALYSIS defines the scope and elementary principles of this broad area of mathematical science which is associated with much of the modern progress in physics and mechanics. Of special interest to physicists and engineers are TENSOR ANALYSIS and VECTOR ANALYSIS.

The statistical techniques applied in quantum mechanics are described under that title, and in PROBABILITY; STATISTICAL MECHANICS; and UNCERTAINTY PRINCIPLE. Other statistical discussions include ERRORS, THEORY OF; PROBABILITY, MATHEMATICAL; STATISTICS; STATISTICS, MATHEMATICAL; RANDOMIZATION; MEAN; PERCENTAGE; STANDARD DEVIATION.

GAMES, THEORY OF, deals with techniques acquired in the analysis of simplified versions of games, and their application.

The philosophical structure of mathematical theory is discussed in LOGIC and LOGIC, HISTORY OF.

The principles on which modern electronic computers are based are outlined in COMPUTER. Related topics include AUTOMATION; BINARY NUMBERS; INFORMATION THEORY; and SERVOMECHANISM. Articles devoted to mathematical aids include GRAPH; LOGARITHMS; NOMOGRAPHY; MATHEMATICAL INSTRUMENTS; MATHEMATICAL TABLES; and SLIDE RULE. Visual aids are described in MATHEMATICAL MODELS.

Biographical articles contain a wealth of material on the origin of mathematical ideas and the relationship between mathematics and other fields of study. Much of the philosophy of mathematics is reflected in such articles as EINSTEIN, ALBERT; FOURIER, JEAN BAPTISTE JOSEPH; GAUSS, (JOHANN) CARL FRIEDRICH; LAPLACE, PIERRE SIMON; NAPIER (NEPER), JOHN; NEWTON, SIR ISAAC; POINCARÉ, (JULES) HENRI; RUSSELL, BERTRAND ARTHUR WILLIAM RUSSELL; and WHITEHEAD, ALFRED NORTH.

The importance of mathematical relationships as clues to the patterns of nature was sensed intuitively many centuries before it was rigorously explored. This provided the stimulus for superstitious beliefs but also for some important discoveries, as noted in PYTHAGORAS and PYTHAGOREANISM and MAGIC SQUARE.

The articles cited above are merely examples of the *Encyclopædia Britannica's* treatment of various fields of mathematics. For a comprehensive list of articles and sections of articles dealing with each mathematical topic, the Index should be consulted.

MATHEMATICS, FOUNDATIONS OF. The study of the foundations of mathematics has dealt with the concepts, and the assumptions about those concepts, with which mathematics starts. Especially since 1900, foundational investigations have come to include also an inquiry into the nature of mathematical theories and the scope of mathematical methods.

THE AXIOMATIC METHOD

Geometry According to Euclid.—Euclid's *Elements* (c. 300 B.C.) is a treatise on the foundations of mathematics as well as on geometry, which is said to have had a greater circulation than any book in history except the Bible. Euclid employs the deductive method, which had come down from Pythagoras two centuries earlier.

First, Euclid introduces fundamental concepts such as point, line, plane, and angle. He relates these to physical space by such "definitions" as "A line is length without breadth"; but since their definitions play no further role in his system, they constitute primitive or undefined terms.

Second, Euclid asserts certain primitive propositions or postulates (*q.v.*) about these primitive terms. These are propositions which the reader is asked to accept as true immediately on the basis of the "definitions" of the primitive terms relative to the physical world.

Third, Euclid deduces further propositions, called theorems, such as the theorem of Pythagoras, "The sum of the squares constructed on the arms of a right triangle is equal to the square constructed on the hypotenuse." That is, he shows that their truth follows logically from the truth of the primitive propositions. While doing so, he also introduces defined terms, such as triangle,

right triangle, and hypotenuse, which are single words that take the place of phrases using besides ordinary language only the undefined terms.

The net result is that the reader, starting with postulates of which he is supposed to be immediately convinced, is led, by a long series of simple steps each intended to be convincing, to accept the truth of other propositions of which he would be far from convinced had they been asserted at the outset. (See LOGIC, HISTORY OF.)

Non-Euclidean Geometry.—Euclid's parallel postulate, on which depends the theorem "Through a point P not on a line L there can be drawn exactly one line parallel to L ," had seemed less evident than his other postulates. Attempts to prove it as a theorem from the other postulates culminated in the discovery published by Nikolai Ivanovich Lobachevski in 1829 and Johann Bolyai in 1832 that a different parallel postulate can be substituted to give a non-Euclidean geometry in which instead "Through a point P not on a line L there can be drawn infinitely many different lines parallel to L ."

Insofar as Euclidean geometry fits physical space, it is impossible to say that the geometry of Lobachevski and Bolyai does not also fit. It is only necessary that the discrepancies between the two be too small to show up in any measurements we can make. So while Euclid thought of his geometry as a true description of physical space, we are obliged to regard it as one of a number of different possible mathematical models of that space.

That a theorem of Euclidean geometry be exactly true can only be a property of the geometry as a logical structure. Now a person who accepts Euclidean geometry as a valid logical structure is equally obliged to accept the geometry of Lobachevski and Bolyai. For example, as Felix Klein observed in 1871 (and Eugenio Beltrami in somewhat different terms in 1868), the postulates of Lobachevski and Bolyai's plane geometry are true in Euclidean plane geometry, when in those postulates the plane is interpreted to be the interior of a circle, the lines to be the chords of that circle, and congruence, distance and angle are defined by a method given by Arthur Cayley in 1859. (See GEOMETRY.)

Formal Axiomatic Method.—Here we have varied the meaning of the undefined terms of a postulational theory while holding the deductive structure fixed, a procedure which is characteristically modern. One can deduce a theory from its postulates without saying at all what the undefined terms are to mean. Then the theory applies to any system of objects which, when taken as the meanings of the undefined terms, make the postulates true.

Indeed, in a postulational theory, one should be able to perform the deductions treating the undefined terms as meaningless. For if their meanings had to be used, whatever had to be taken from their meanings should instead be provided by additional postulates. In Euclid's *Elements* some properties of the undefined terms did in fact enter from their meanings via the figures. These hidden assumptions were brought to light and stated as postulates by Moritz Pasch (1882) and by David Hilbert (1862–1943) in his *Grundlagen der Geometrie* (1899). Thus Hilbert states as a postulate, "If a line L cuts the side AB of a triangle ABC and does not pass through A , B or C , then it must also cut AC or BC ."

The postulational method when the undefined terms are treated as meaningless is called the formal postulational method, or formal axiomatic method as in this connection axiom (*q.v.*) and postulate are often used synonymously, in contrast with the material axiomatic method of Euclid. Formal axiomatics is represented par excellence by Hilbert in the work cited.

It might be thought that meaninglessness of the undefined terms would rob a theory of its interest, but the opposite can be the case. Thus for some theories many different interpretations of their undefined terms each make the postulates true (e.g., Euclidean geometry without the parallel postulate, or in algebra abstract groups). The deduction of such a theory independently of any interpretation makes it a mathematical tool prepared in advance for diverse applications. If in essential respects only one such interpretation exists, the postulates are categorical (*q.v.*). If there is no such interpretation, the theory is without value, and one of the problems for foundations is to exclude such theories.

THE GENETIC METHOD

Arithmetic, Analysis.—Systems of numbers are more often introduced by the genetic method, so-called by Hilbert (1900). In this the objects are generated or constructed in a certain orderly manner, and the theorems express properties of the system of the objects assured by this mode of generation. Of course deductive reasoning is used, just as in the axiomatic method, to obtain unobvious properties from obvious or immediate ones, and the immediate properties can be listed as postulates. Thus the natural numbers 1, 2, 3, . . . , used in counting discrete objects, are describable genetically as the objects which are generated by starting with a first object 1 and by proceeding from any object n already generated to a next object $n + 1$, objects differently generated being distinct. A suitable selection of immediate properties constitutes the five postulates of Giuseppe Peano (1889), which are categorical for the arithmetic of the natural numbers. By starting from these postulates, rather than from the generation, that arithmetic can then be considered as a formal axiomatic theory. But we shall continue here with the genetic method in describing some other mathematical systems of objects.

Arithmetic (*q.v.*) has several senses; but one of them is the theory of the natural numbers, and of similar systems of numbers, such as the (rational) integers . . . , -2 , -1 , 0 , 1 , 2 , . . . , or the rational numbers which are the numbers expressible as fractions p/q where p and q are integers and $q \neq 0$.

Analysis (*q.v.*) deals with such systems of objects as the real numbers, used in the measurement of continuously variable magnitudes. A theory of real numbers not resting on vague geometrical imagery was only achieved in the latter part of the 19th century, by K. T. W. Weierstrass, Julius Dedekind, Charles Méray and G. F. L. P. Cantor. The version using infinite decimals will suffice here. For example, $\frac{1}{4} = 2.25 = 2.24999$, . . . , $-\frac{1}{4} = -2.25 = -3 + .75 = -3 + .74999$, . . . , $1 = 0.99999$, . . . , $\sqrt{2} = 1.41421$, . . . , $\pi = 3.14159$, In each example, a real number x is expressed as a sum $X + .x_0x_1x_2x_3x_4 \dots$ of an integer X and a nonterminating decimal fraction $.x_0x_1x_2x_3x_4 \dots$ (*i.e.*, one without all digits 0 after some place). The real numbers are given genetically, each number uniquely, as all possible such sums.

Cardinal Number, the Theory of Sets.—Imagine a tribe of aborigines, unable to count above 20, whose chief is by custom their member with the most numerous herd. If there were two contenders for the chieftaincy, the tribe could decide the winner (or that the two contenders are tied) by passing their herds through a gate, a pair of animals one from each herd at a time.

Cantor was the first who applied this idea systematically to the comparison of infinite collections. A one-to-one correspondence between two collections or sets of objects S and T is a collection of ordered pairs in which the first member of each pair belongs to S , the second member to T ; and each member of S occurs as first member, each member of T as second member, of just one pair. Two sets have the same cardinal number if there is a one-to-one correspondence between them.

The natural numbers 0, 1, 2, . . . , the positive integers 1, 2, 3, . . . , the squares of the positive integers 1, 4, 9, . . . (an example used by Galileo Galilei in 1638), and the integers 0, 1, -1 , 2, -2 , . . . have the same cardinal number. Infinite sets with this cardinal are countable (or countably infinite, to distinguish them from finite sets which are also countable), since they can be counted off or listed by using the natural numbers. A fifth example of a countably infinite set is the rational numbers; for each rational can be written as $(-1)^n p/q$ with the least possible natural numbers n , p , q , and then the rationals can be enumerated in the order of magnitude of the positive integers $2^3 3^5 5^7$.

A part or subset of a set S is a set each member of which is a member of S . As Galileo had noted, a part not the whole of an infinite set can be in one-to-one correspondence with the whole. (Dedekind in 1888 used this property to distinguish infinite sets from finite sets.) A set T is of greater cardinal number than another set S , if there is a one-to-one correspondence between S and a subset of T but not vice versa.

Cantor showed in 1874 by his diagonal method that there are sets of greater cardinal number than the natural numbers. A

(single-valued) number-theoretic function f of one variable x is a correspondence by which, to each natural number x , there corresponds a unique natural number $f(x)$, called the value of f for x as argument. The set of these functions is uncountable. For consider any infinite list f_0, f_1, f_2, \dots of such functions. Then the function f defined by $f(x) = f_x(x) + 1$ (so the values of f come by altering every value in the diagonal, if the values of f_0, f_1, f_2, \dots have been written in successive rows) is not in the list; for if f were f_0 , the contradictory equation $f_0(q) = f_0(q) + 1$ would be obtained upon taking the value for q as argument. The set of these functions is of greater cardinal number than the natural numbers; for on the other hand, the natural numbers n are in one-to-one correspondence with the constant functions $f(x) = n$.

In our generation of the real numbers, the nonterminating decimals can be construed as number-theoretic functions taking values ≤ 9 ; so the reals are uncountable, by reasoning the same as above except taking $f(x) = 8$ when $f_x(x) = 9$.

A given set of natural numbers is represented by a function which takes 0 or 1 as value according as the argument is in the set or not; so the sets of natural numbers are uncountable, by reasoning the same as above except taking $f(x) = 0$ when $f_x(x) = 1$.

It is not hard to show that these three uncountable sets have the same cardinal. The third illustrates Cantor's theorem, "The cardinal number of the set of the subsets of a set S is greater than the cardinal number of S ."

Thus infinity is not simple, but indeed there are a whole host of infinite or transfinite cardinal numbers. This is only one of the results of Cantor's theory of sets, which greatly extended the mathematical horizon, besides seeming to provide the ideas for a general foundation of mathematics.

THE CRISIS IN FOUNDATIONS FOLLOWING 1900

The Paradoxes.—Already in the last decade of his scientific life Cantor became aware that his theory of sets pushed too far leads to contradictions; we describe two (*see* ANTINOMY).

Let S be the set of all sets, and T the set of the subsets of S . Since T corresponds one-to-one to itself as a subset of S , it cannot have a greater cardinal than S . Yet by Cantor's theorem it must; this is Cantor's paradox (1899).

The phrases in the English language are countable. After listing all the phrases, strike out those which do not define number-theoretic functions. Application of Cantor's diagonal method to the list remaining enables one to define in the English language a function which differs from every function definable in the English language. This paradox was found by J. A. Richard (1905).

These modern paradoxes have a counterpart in the ancient paradox of the liar, which in one form appears in a paradoxical statement attributed to Epimenides (6th century B.C.?) and in another is attributed to Eubulides (4th century B.C.) who has a person say, "What I am now saying is a lie." The quoted sentence if true must by what it says be false, and if false be true.

No one has succeeded in disposing of the paradoxes by simply pointing out a fallacy upon which all can agree.

Cantor's paradox is evidently connected with the use of too large sets. But where shall a line be drawn? And what definition of set shall replace Cantor's as "any collection of definite well-distinguished objects of our perception or our thought into a whole?"

In fact it is possible to reformulate set theory to exclude too large sets. In doing so, axioms are listed to govern just what sets shall be allowed; and set theory becomes a formal axiomatic theory instead of a genetic one. The first system of axiomatic set theory was given by Ernst Zermelo in 1904 and improved by Adolf Fraenkel and Thoralf Skolem in 1922-23. Axiomatic set theory provides probably the simplest system in which most existing mathematics, but not the paradoxes as far as is known, can be deduced. Kurt Gödel in 1938 showed that Cantor's continuum hypothesis, "The cardinal number of the real numbers is the least cardinal number greater than that of the natural numbers," which no one has succeeded in proving up to the 1960s, can be added as a new axiom to set theory without introducing contradiction.

That the paradoxes arose shows there is some defect in the

methods, which hitherto had been trusted, of constructing and reasoning about mathematical objects. Transforming the theory of sets from a genetic into a formal axiomatic theory leaves over the problem of whether there is an interpretation of the undefined terms which makes the axioms in some sense true. To ignore these issues is to adopt a mathematical nihilism. Formally axiomatized mathematics cannot be all of mathematics. To draw upon another formal axiomatic theory for such an interpretation is a regress. At some level there must be a meaningful mathematics. At the very least we must believe that the theorems of a formal axiomatic theory really do follow from the axioms. As a further example, when mathematicians say that by a certain method it can be determined in a finite number of steps whether an equation $ax + by + c = 0$ with given integral coefficients a, b, c has a solution for x, y in integers, they certainly do not mean merely that this proposition can be deduced from certain axioms.

Henri Poincaré and Bertrand Russell about 1905 concluded that the explanation of the paradoxes lies in a certain circularity of definition. When a set M and an object m are so defined that m is a member of M but is defined only by reference to M , the definition of M or of m is called impredicative. An impredicative definition can be found in each of the paradoxes. Thus the sickness of mathematics could be cured by banning impredicative definitions, if it did not inconveniently turn out that the cure would kill the patient. For, as was especially emphasized in Hermann Weyl's *Das Kontinuum* (1918), there are impredicative definitions also in analysis.

Three main schools of thought have arisen which have provided both a philosophy of mathematics and a development of mathematics based upon it.

Logicism.—The logicistic thesis is that mathematics is a branch of logic. Gottfried Wilhelm Leibniz in 1666 had conceived of logic as a universal science embracing the principles underlying all others. Dedekind (1888) and especially Gottlob Frege (1884, 1893) derived arithmetic from logic. The thesis that all of mathematics is reducible to logic alone is due to Russell.

Russell, after rediscovering results of Frege, had to make provision against the paradoxes. This provision took the form of a ramified theory of types. Roughly described, the primary objects not being subjected to logical analysis he took to be of one type, say type 0, properties of objects of type 0 to be of type 1, properties of properties of type 1 to be of type 2, etc.; and he excluded from use any properties not belonging to one of these types. Then to exclude impredicative definitions within a type, he separated the types above type 0 into orders, the properties defined using the totality of properties of a given order being placed in the next higher order. Finally to overcome the obstacle which exclusion of impredicative definitions opposes to analysis, he postulated his axiom of reducibility, which asserts that to any property belonging to an order above the lowest there is a property of order 0 possessed by exactly the same objects.

On this basis, mathematics was deduced from logic, in a symbolic language, in the monumental *Principia Mathematica* by Alfred North Whitehead and Russell (3 vol., 1910–13).

The use of the axiom of reducibility weakens the case for the logicistic thesis. For if the axiom be true, should not the reductions to order 0 be constructed instead of being merely postulated as existing? Weyl hence remarked (1946) that in *Principia Mathematica* "mathematics is no longer founded on logic, but on a sort of logician's paradise."

Leon Chwistek (1921) and F. P. Ramsey (1926) introduced a simple theory of types in which the separation into orders is suppressed. This still allows the deduction of mathematics from logic, with the paradoxes apparently excluded, but it does not improve the philosophical position.

A fundamental objection to the logicistic thesis is posed by the intuitionists (see below), who find an essential mathematical kernel in the idea of iteration, which already has to be used in establishing the hierarchy of types and even in listing the propositions in a proof.

Willard Van Orman Quine (1937) weakened the type restriction to one of stratification. The resulting system is a form of axio-

matic set theory rather than of type theory. Indeed, though the logicistic thesis did not so develop historically, it could be based as well on a set theory as on a type theory.

Intuitionism.—In the 1880s Leopold Kronecker had objected to the methods of Weierstrass, Dedekind and Cantor in that their fundamental definitions are only words since they do not enable one in every case to decide whether a given object satisfies the definition.

In 1908, in a paper on the untrustworthiness of the principles of logic, L. E. J. Brouwer challenged the belief that the laws of the classical logic as they have come down to us essentially from Aristotle (4th century B.C.) have an absolute validity, independent of the subject matter to which they are applied.

In particular, Brouwer refuses to accept the law of the excluded middle, "Either A or not- A ," as valid for all A 's. Suppose A is "There exists a member of the set S having the property P ." Then not- A is equivalent to "Every member of S lacks the property P ." Thus the law of the excluded middle would give "Either there is a member of S with the property P , or every member of S lacks the property P ," call this M . Suppose it is possible in principle to decide, for any given member of S , whether it has property P . Then if S is finite, it is possible in principle, by examining each member of S in turn, either to find a member of S with property P or to verify that every member of S lacks property P , though it might be impracticable to complete the examination for large S or even for small S if the determination for some members whether they have property P is lengthy. On the basis of this possibility, Brouwer accepts the truth of M for such P and finite S . But when S is infinite, the described examination cannot in principle be completed; if in pursuing it one has come upon a member of S with property P , the first alternative is substantiated, but if at any stage of the examination a member with property P has not yet been found, one does not know whether it is because there is none or because he has not persisted long enough. In some examples the second alternative might be substantiated by deducing a contradiction from the supposition that an arbitrary member of S has property P . This is the case when S is the set of pairs (p, q) of positive integers and P the property that $p^2 = 2q^2$, as was discovered by Pythagoras in the 6th century B.C. (i.e., $\sqrt{2}$ is irrational). But take the case that S is the quadruples (x, y, z, n) of positive integers with $n > 2$, and P the property that $x^n + y^n = z^n$. About 1637 Pierre de Fermat wrote that he had a proof of the proposition that every member of this S lacks this property P , which is known as Fermat's last theorem (q.v.). He did not record his proof, and no one has since been able to find a proof or a counter-example, though immense effort has been expended. We know of no method which must resolve the question if pursued long enough. Brouwer says that M can only mean that one can in principle find out that one or the other alternative is true; and in the face of examples for infinite S in which we have no assurance that we can, he declines to accept M , and hence also the law of the excluded middle, as a universally valid principle of logic.

Similarly, for Brouwer a statement that an object exists having a given property means that, and is only proved when, a method is known which in principle would enable such an object to be found or constructed. Thus he does not accept indirect existence proofs, which consist in deducing a contradiction from the assumption of nonexistence.

In classical mathematics, i.e., mathematics as based on the classical logic, infinite sets are treated as though they could be given completely, whereas Brouwer admits only a potential infinite. The concept of the natural number sequence 0, 1, 2, . . . has its origin, as he sees it (1907), in our capacity to distinguish one sensation as it recedes into the past and is retained by memory from another which replaces it, and to imagine an unlimited repetition of this process. The sequence 0, 1, 2, . . . is thus only "a manifold of possibilities open towards infinity" (Weyl, 1946).

For Brouwer, neither language nor logic is a presupposition for mathematics, which has its source in an intuition that makes its concepts and inferences immediately clear to us.

Most theorems of classical arithmetic can be established intuitionistically. But Brouwer's critique affects the whole

methodology of classical analysis. Thus to say that any two real numbers x and y are either unequal or equal is to say that either there exists, among the integer of x and successive digits of x , one which is different from the corresponding one of y , or that all are the same. This is an application of the law of the excluded middle of the kind which Brouwer eschews.

Brouwer developed an intuitionistic mathematics, including an analysis and set theory (1918-24). This is interesting in itself, but too different and too complicated to serve as a substitute for classical mathematics satisfactory to most mathematicians or to be practically usable in the natural sciences. But his insights have played an important role in foundational investigations.

Formalism.—Hilbert accepted that the parts of classical mathematics which employ the completed infinite go beyond intuitive evidence. But instead of rejecting those parts, he proposed, roughly, to formulate classical mathematics up to a suitable point as a formal axiomatic theory, and to prove this theory consistent, i.e., free from contradiction.

Previous to this proposal of Hilbert's (1905, and more specifically from 1918 on), proofs of consistency had been given for axiomatic theories by interpreting their undefined terms in another theory so that the axioms become true, or briefly by giving a model. Thus the plane Lobachevskian geometry was interpreted in Euclidean geometry by Beltrami. The consistency of geometries generally is reduced to that of analysis by René Descartes' analytic geometry (1637), which employs real numbers as co-ordinates of points, so that geometrical propositions become propositions in the algebra of real numbers. For proving the consistency of analysis itself, the method of models offers no hope, since no theory is available in which analysis could be interpreted which appears safer than analysis.

Hilbert's proposal called for proving consistency by a new method based directly on the meaning of consistency as freedom from contradiction. Not only should all the mathematical assumptions of a theory be listed, but also all of the principles of logic, both the primitive propositions and the rules for drawing inferences, to be used in deducing theorems from the mathematical postulates. This done, one could undertake to show that no two proofs in the theory terminate in theorems one of which is the negation of the other. Hilbert would thus make the proofs of the formal theory the object of an intuitive theory, called proof theory or metamathematics. The latter should use only intuitively convincing methods, called by him finitary methods. These methods in practice are intuitionistic methods on the level of number theory. The formal theory provides a sort of stereotyped model of the previously existing informal theory, which is called the interpretation of the formal theory. This interpretation should play no role in the metamathematics, though it motivates the choice of the particular formal theory which is the object of the metamathematics.

To guarantee that all the principles of logic used in deducing theorems have been listed as axioms and rules of inference, the meanings of all the words should be left out of account in deducing theorems, just as in a formal axiomatic theory it should be possible to leave out of account the meanings of the undefined mathematical terms. Because of the irregularities and ambiguities of the existing word languages, it is only feasible to do this by reconstructing the informal theory as a symbolic language, which can be done by combining symbolic logic with the symbolization common in modern mathematics. The resulting formal theory is called a formal system or logistic system, a statement in it a formula (or by some writers a well-formed formula, to emphasize that it must be formed from the symbols by listed formation rules), and the method the logistic method. The description of a formal system must be given from outside in an informal theory. The method was already available, but Hilbert added the proposal to make the formal system the object of mathematical investigations in this informal theory or metamathematics.

There ensued a controversy in which Brouwer questioned how a metamathematical proof of consistency of classical mathematics would meet the objection that the propositions of classical mathematics beyond a certain elementary level lack a clear intuitive

meaning. The upshot was that the intuitionists would accept Hilbert's program as unobjectionable, provided the formalists refrain from construing a consistency proof as in some manner vindicating classical mathematics intuitively. Hilbert drew an analogy with the stratagem in mathematics of adjoining ideal elements to a previously constituted system to achieve some theoretical end (e.g., the irrational numbers were added to the rationals so that all convergent sequences should have limits, the imaginary numbers to the reals so that all algebraic equations should have solutions; see NUMBER). He called the statements of classical mathematics with an intuitive meaning real, the others ideal. The statements involving the completed infinite are ideal. So he said, in classical mathematics the ideal statements are adjoined to the real to give the theory as a whole a simpler logical structure, and it is no more reasonable to require that each separate statement should be interpretable taken by itself, than that in theoretical physics each separate statement should be verifiable by experiment. The possibility appeared that classical mathematics reinforced by a proof of consistency might even serve as a tool for the intuitionistic proof of real statements via short cuts through the ideal statements.

Hilbert's program was undertaken by him, Paul Bernays, Wilhelm Ackermann, John von Neumann, and others after 1920. The start was made by investigating a formal system of classical arithmetic (with several variants), obtained by adding Peano's postulates and definitions of sum and product to the first-order functional calculus, as described in Hilbert and Bernays' *Grundlagen der Mathematik* (2 vol., 1934 and 1939). A proof by Ackermann in 1924-25 of consistency of a subsystem did not lead at once to a proof of consistency of the whole system. Then in 1931 results of Gödel appeared which clarified the situation, and which we present below from a standpoint reached after 1935. The metamathematical method proved valuable for a variety of purposes in studying formal systems generally, as well as the ones Hilbert considered. Thus a formal system of intuitionistic logic and mathematics was described by Arend Heyting in 1930.

COMPUTABILITY AND DECIDABILITY

Decision Problems, Church's Thesis.—For certain classes of questions in mathematics, a method is known which can be applied to answer by yes or no any given question of the class. For example, for any positive integers a and b , the question "Is a a multiple of b ?" can be answered by dividing a by b and seeing whether the remainder is 0 or not. As a less obvious example, there is a method for deciding, for any given integers a, b, c , whether $ax + by + c = 0$ has solutions for x, y in integers. Such a method is called an algorithm or decision procedure; and the problem of finding such a method for a class of questions is called the decision problem for that class. Similarly, for a class of questions which require for their answers, not yes or no, but the exhibiting of some object, we speak of an algorithm or computation procedure, and a computation problem.

In the logistic method, the description of a formal system must enable one to decide whether any given formula is an axiom, and whether any given formula comes by a permitted inference from one or two others; so there is a decision procedure for whether a given finite list of formulas is a proof in the system. But a decision procedure is not thereby provided for whether a given formula is provable, i.e., for whether there is a proof of it. The problem of finding a decision procedure for the latter is often called the decision problem for the formal system, and was recognized as a problem of logic by Ernst Schröder (1895), Leopold Löwenheim (1915) and Hilbert (1918). Emil L. Post (1921) gave a decision procedure for the classical propositional calculus.

A decision procedure for a formal system embracing a given portion of mathematics would make automatic the solution of any problem in that portion statable as a yes or no question. It is therefore implausible that there should be a decision procedure for a formal system embracing the usual arithmetic, in view of the experience of mathematicians in trying to solve the one particular problem whether Fermat's last theorem is true; and many other similarly refractory problems are known. For there to be a de-

cision procedure would mean, so to speak, that the infinitely many arithmetical problems involve only a finite number of difficulties such that once those are overcome no further ingenuity will be required. But it might have seemed equally farfetched in 1918 to hope that mathematics could get a hold on the problem of finding a decision procedure for arithmetic, which would enable this problem to be solved by showing that there cannot be one. Exactly this latter was done in 1936 by Alonzo Church.

We begin by considering the computation problems for number-theoretic functions. What functions can be computed or effectively calculated, in the sense that, for a given argument, the value can be found by use only of preassigned rules, applicable without ingenuity on the part of the computer? Instead of a human computer, we can propose to have a machine to do the computation, according to rules built into its structure.

As this description is somewhat vague, what is needed is an exact mathematical formulation which comes to the same. Such a formulation was given briefly by Post in 1936 and independently in detail by Alan M. Turing (1936-37). What Turing did was to describe a kind of theoretical computing machine, not limited in use by a fixed maximum amount of storage of information nor liable to malfunctioning, as are actual computing machines. A Turing machine operates in the following manner. At discrete moments the machine assumes one of a finite list of states (fixed for a given machine), the first of which we call the passive state, the other k (≥ 1) active. A linear tape, potentially infinite to the right, is ruled in squares, each of which is either blank or has printed upon it one of a finite number j (≥ 1), of symbols (fixed for a given machine), including say the tally $|$; but only a finite number of squares are printed. The tape passes through the machine so that one of its squares is scanned. If at the given moment the machine is in an active state, then it can alter the condition of the scanned square (by erasing, printing, or both), and/or move the tape so that the scanned square becomes the one next right or left, and/or change to another state, between the given moment and the next; this act is determined (for a given Turing machine) by the state of the machine and the condition of the scanned square at the given moment.

Turing used his machines primarily to compute in succession the digits of decimal expansions of real numbers, but they can be adapted to compute number-theoretic functions. Let an argument x be supplied to the machine by placing a blank followed by $x+1$ tallies on successive squares of the tape starting with the leftmost square, leaving the tape otherwise blank, and placing the tape in the machine with the rightmost tally scanned and the machine in its first active state. The machine is said to compute a value y for x as argument, if then it eventually reaches the passive state with the $x+1$ tallies followed immediately to the right by a blank and $y+1$ tallies, the rightmost being scanned and the tape being otherwise blank. If, for each natural number x , the machine computes the correct value $y = f(x)$ of a function f , when supplied the argument x , it computes the function f , which is then said to be Turing computable.

Turing advocated the thesis that any function which can be effectively calculated is Turing computable. His arguments include showing that various operations that a human computer can perform can be analyzed into successions of the simple operations his machines perform. Church had already in 1936 proposed the thesis that every effectively calculable function is λ -definable in a sense due to Church and Stephen C. Kleene, or equivalently general recursive in a sense due to Goedel, who built on a suggestion of Jacques Herbrand; and this thesis was subsequently proved equivalent to Turing's, so the λ -definable functions, the general recursive functions, and the Turing computable functions are the same.

Church's Theorem.—The pattern of behaviour of a Turing machine is completely described by a $k \times (j+1)$ table showing the act to be performed for each of the k active states with each of the $j+1$ conditions of the scanned square. A system for encoding such tables can be established which, to each table, gives a natural number t as code number so that a person who knows the system can from t find the table and thence the behaviour of a machine M_t with this table. If t is the code number of a machine M_t which

computes a value for x as argument, let $f_t(x)$ be this value; and let $f_t(x)$ be undefined otherwise.

Consider the function f defined by letting $f(x) = f_x(x) + 1$ if $f_x(x)$ is defined, and $f(x) = 0$ otherwise. This function f is not computable. For if machine M_q with code number q computes a value for q as argument, that value is $f_q(q)$, not $f_q(q) + 1$ as it would have to be if M_q computes f . It follows that the property " $f_x(x)$ is defined" is undecidable. For otherwise we could compute $f(x)$, given x , thus: first decide whether $f_x(x)$ is defined; then if it is, imitate the behaviour of M_x to compute it and add 1; if it is not, write 0.

Thus from Turing's thesis we have proved that there is a class of quite elementary arithmetical questions for which there is no decision procedure. This essentially is Church's theorem (1936), which he proved from his thesis using a corresponding class of questions in terms of λ -definability: For each x , the proposition " $f_x(x)$ is defined" is expressible in any formal system S which includes the usual vocabulary of arithmetic, by a formula A_x effectively determinable given x . If the quoted proposition is true, it is demonstrable intuitively by exhibiting the sequence of the acts of machine M_x in computing $f_x(x)$. Suppose S includes ordinary arithmetical reasoning; then that demonstration can be translated into a proof in S of A_x ; i.e., A_x is provable in S whenever (the proposition expressed by it is) true. Finally suppose about S that A_x is provable in S only when true. Then there can be no decision procedure for provability in S ; for if there were, by answering the question whether A_x is provable in S , we would have a decision procedure for " $f_x(x)$ is defined."

Moreover there is no decision procedure for the important logical system F of first-order functional (or predicate) calculus, as Church (1936) and Turing (1936-37) showed. For a proof of A_x in S can be arranged as a deduction by F of A_x from a suitable finite set of arithmetical axioms independent of x , the conjunction of which can be written as one formula C . If the symbolism has been suitably chosen, then A_x is provable in S , if and only if the implication $C \supset A_x$ is provable in F . From these beginnings, a considerable theory has grown about "unsolvable decision problems," with further contributions by Post, A. A. Markov (the younger), Turing, Alfred Tarski, Andrzej Mostowski and P. S. Novikov.

Goedel's Theorem.—A formal system like S is consistent, if for no formula B are both B and its negation $\sim B$ provable in S , complete, if for each formula B without free variables (otherwise $\sim B$ may not express the opposite of B) either B or $\sim B$ is provable in S .

Now suppose further that $\sim A_x$ is provable in S only when true. Then it is absurd that S be complete (and that $\sim A_x$ be provable in S whenever true). For A_x is provable in S (when and) only when true. So if, for each x , either A_x or $\sim A_x$ were provable, we could decide whether $f_x(x)$ is defined or not, by searching through all the proofs in S till we find one of A_x or of $\sim A_x$. This is Goedel's theorem (1931) in a negative form.

To obtain the positive form, consider the process, for a given x , of searching through all the proofs in S for one of $\sim A_x$, and writing 0 if one is found. A Turing machine, say machine M_q with code number q , carries out this process, when supplied with x . Now by the choice of the formulas A_x , $\sim A_q$ is true if and only if $f_q(q)$ is undefined, which by the choice of M_q is the case if and only if $\sim A_q$ is unprovable in S . In brief, $\sim A_q$ expresses its own unprovability (cf. the paradox of the liar). So were $\sim A_q$ provable, it would be false, contradicting our supposition that $\sim A_x$ is provable only when true. So $\sim A_q$ is unprovable but true, and A_q is also unprovable (since false).

Hilbert's program called for embodying classical mathematics, including arithmetic, analysis, and set theory short of the paradoxes, in a formal system, and proving that system consistent by finitary methods. The part of Goedel's theorem that $\sim A_q$ is unprovable but true shows that not even the first step can be carried out fully. Despite the great value of the logistic method as a way of defining exactly the presuppositions of a given portion of mathematics, this very process of definition restricts that portion to include less of arithmetic than free use of intuitive reasoning would give, at least if what is already incorporated in the formal system is intuitively correct.

The part of the theorem that neither $\sim A_0$ nor A_0 is provable in S shows the inadequacy of S to decide by proof or disproof, irrespective of the interpretation, all the statements expressible in it. Thus A_0 is said to be formally undecidable in S .

In showing $\sim A_0$ unprovable (and true), we used (for $z = q$) the assumption that $\sim A_0$ is provable in S only when true. This can be replaced by the metamathematical assumption (not ostensibly using the interpretation) that S is consistent. For if $\sim A_0$ were provable, $f_q(q)$ would be defined, and hence as noted above A_0 would be provable, which would contradict the consistency.

(The assumption that A_0 is provable only when true, used in showing A_0 unprovable, can be replaced by the assumption that S is ω -consistent, in the sense that for no formula $B(x)$ are $B(0)$, $B(1)$, $B(2)$, . . . and $\sim(x)B(x)$ all provable in S , where " (x) " expresses "for all x ." In verifying this, $B(x)$ will express "at the x -th moment M_0 has not yet computed $f_x(q)$." Adjoining A_0 to S as a new axiom produces a formal system which is consistent but not ω -consistent, if S is consistent. Barkley Rosser in 1936 modified Goedel's formally undecidable formula so that consistency sufficed; in fact, letting M_x carry out the process of searching through all the proofs in S for one of $\sim A_0$ and writing 0 if one is found before one of A_0 is found, $\sim A_0$ is unprovable but true and A_0 is unprovable, if S is consistent.)

As Goedel observed in proving his theorem, the objects employed in a formal system, say S , are countable; and after correlating natural numbers (called now Goedel numbers) effectively to them, by talking about those numbers instead of the formal objects, the metamathematics of S becomes a part of arithmetic and so expressible in S . Now consider the implication "If S is consistent, then $\sim A_0$ is true," obtained above as part of Goedel's theorem. Let Cons_S be the formula of S which expresses " S is consistent" in S via the Goedel numbering. Then the quoted implication translated into S becomes $\text{Cons}_S \supset \sim A_0$. Goedel claimed that, by imitating formally in S the intuitive proof of his theorem, it should be possible to prove this formula in S . (This was done in detail by Hilbert and Bernays in 1939 in their formal system of arithmetic.) But then, if Cons_S were also provable, $\sim A_0$ would be, which is contrary to Goedel's (first) theorem if S is consistent. Thus Goedel obtained his second theorem: If S is consistent, then the formula Cons_S , which says in S via the Goedel numbering that S is consistent, is unprovable in S .

Goedel's second theorem raises an obstacle to the second part of Hilbert's program. One might have supposed that the finitary methods to be used in proving consistency would be part of the methods formalized in the system, which amounts to saying that a finitary proof of consistency of S should be formalizable as a proof in S of Cons_S . Only such methods appear to have been used in attempts prior to 1931. Goedel's second theorem shows that not even all the methods incorporated in S , including the nonfinitary ones, would suffice.

Some mathematicians felt that this ended once and for all Hilbert's plan to make classical mathematics more secure by a consistency proof. Others thought it possible that methods might be found for proving consistency, which, though not formalizable within S , could be construed as finitary and thus as safer than some of the methods incorporated in S . Thus Gerhard Gentzen in 1936 gave a proof of the consistency of a system S of classical arithmetic, in which the nonelementary method (not formalizable in S) is an extension of mathematical induction ($q.v.$) from the natural number sequence to a certain segment of the transfinite ordinal numbers which Cantor had introduced for extending the counting process beyond that provided by the natural numbers.

Further Perspectives.—Goedel's (first) theorem provided confirmation for the view advanced earlier by the intuitionists on philosophical grounds that the possibilities for intuitive mathematical thinking cannot be circumscribed in advance. Taking Brouwer's interpretation of a statement " $\exists y$ exists such that $P(x,y)$ " as meaning such a y can be found, and applying Church's thesis to the case the y depends on x , Kleene in 1943 proposed the further thesis that a statement "for each x , a y exists such that $P(x,y)$ " is provable intuitionistically only if such a y can be given as a computable function of x . Using this thesis, there are theorems of

classical arithmetic (Kleene, 1943) and of classical analysis (Ernst Specker, 1949) which are unprovable intuitionistically (not merely in some formal system, but absolutely); so classical mathematics reinforced by a consistency proof cannot serve as a tool of intuitionistic proof, except of a very restricted class of statements. Kleene (1945) and David Nelson (1946) together showed that the intuitionistic formal arithmetic based on Heyting's intuitionistic formal logic does conform to the thesis. Goedel in 1932-33 (partially anticipated by Andrei N. Kolmogorov in 1924-25) correlated to each arithmetical formula B a classically equivalent formula B' which is provable in the intuitionistic formal arithmetic if (and of course only if) B is provable in the classical formal arithmetic. In particular, the correlation proves very simply that the classical formal arithmetic is consistent if the intuitionistic is. However, the intuitionistic arithmetic distinguishes differing degrees of indirectness among statements classically equivalent.

Using the classical law of the excluded middle, Goedel in 1930 proved a completeness theorem for the first-order functional calculus F . In one form, this says that if a formal system obtained by adjoining mathematical axioms to F is consistent, it has a model; i.e., there is an interpretation which makes the axioms true. Indeed, the model can be constructed using the natural numbers as the objects. In another form, the theorem says that in such a system every formula is provable which is true under all the interpretations of the undefined terms which make the axioms true. In view of this, when S is based on first-order functional calculus, the unprovability in S of $\sim A_0$ implies that, while $\sim A_0$ is true under the intended interpretation of the undefined terms, there is some other interpretation which makes the axioms true (a nonstandard model) under which $\sim A_0$ is false. This illustrates the theorem of Skolem (1933) that no list of axioms in the symbolism of the first-order functional calculus can characterize the natural numbers categorically. If higher functional calculus is used, the deductive apparatus will be incomplete. It thus appears that the logistic method is inadequate to characterize the natural numbers categorically. Peano's axioms characterize them categorically, but only through an interpretation which cannot be rendered fully through the deductive possibilities. Also we see the Goedel formal undecidability of A_0 as a phenomenon of the same kind as the undecidability of Euclid's parallel postulate from the other postulates of Euclidean geometry.

MATHEMATICS, HISTORY OF. The study of the languages of primitive peoples, as well as related investigations of extinct languages, indicates that a process apparently as simple as counting passed through many stages before it reached a level that permitted the systematization that is essential for any mathematical procedure. Similar observations have been made in the study of early writing. Only tortuous processes led from symbols for sets of concrete objects to a general notation which can be justly called a system of numerals. Mathematics originated only in a very few areas within the framework of highly developed urban civilizations and well-organized economic conditions.

Additional material relating to the following discussion will be found under ALGEBRA, HISTORY OF; ANALYSIS; GEOMETRY; GEOMETRY, NON-EUCLIDEAN; MATHEMATICS, FOUNDATIONS OF; NUMERALS AND NUMERAL SYSTEMS; SCIENCE, HISTORY OF; and in the biographies of the various mathematicians mentioned.

Historical Outlines.—Considering four of the great civilizations of antiquity—Babylon and Egypt, Greece and Rome—two contributed little to the development of mathematics; neither Egypt nor Rome advanced beyond the level of the elementary practical arithmetic and mensuration. Priority in the development of mathematics belongs to Babylonia (and to its Sumerian heritage), where numerical, algebraic and geometrical methods

existed at least since the Hammurabi dynasty (around 1700 B.C.). Little is known about the prehistory or about the subsequent period until Persian times (6th century B.C.). Nevertheless, that the tradition had been kept alive is proved by texts of the latest period of Babylonian history, when the country had come under Greek and then Parthian domination (last three centuries B.C.). Shortly before, during the 5th or 4th century B.C., the rapid development of Babylonian astronomy began, which became the main carrier of Babylonian arithmetical methods over the world—still retained today in the 60 division of hours and degrees. (See BABYLONIA AND ASSYRIA: *Intellectual Achievements*.)

Greek theoretical mathematics began in the 5th and 4th century B.C.—Archytas of Tarentum and Eudoxus of Cnidus were the outstanding representatives of the earliest phase which closed with Euclid in the beginning of the Hellenistic period. The climax of this development was reached about a century later with Archimedes of Syracuse and Apollonius of Perga. The period following Alexander, with the whole Persian empire from India to Egypt under Greek domination, witnessed the assimilation of Babylonian arithmetical methods, particularly in Hellenistic astronomy. Following Apollonius and Hipparchus (about 150 B.C.), geometric methods were applied to the study of eccentric and epicyclic motion, parallel with the development of trigonometry, stereographic projection, etc. The highest peak of this process was reached with Ptolemy of Alexandria in the 2nd century A.D.

Probably around A.D. 400, Hindu astronomy began under western influence. This led to two important modifications of the Hellenistic methods: the replacement of the chord function by the sine function in trigonometry, and the substitution of the decimal for the sexagesimal place-value notation.

In the Islamic period, the meeting of all the preceding forms of mathematical activities, theoretical as well as graphical and numerical methods in astronomy and optics, took place. The "Algebra" of al-Khwarizmi (9th century, Baghdad) continued the near eastern tradition rooted in ancient Mesopotamia, while his astronomy combined Indian and Greek components. After the first great scientific activity declined with the Abbasid dynasty, the centres of Islamic science followed, more or less, the political development. By A.D. 1000 one of the greatest scholars of Islam, al-Biruni, followed Mahmud of Ghazni to India, while the Fatimid court in Egypt counted Ibn Yunis and Ibn al-Haitham among its scholars. Two centuries later, under Frederick II, Sicily came into close contact with Islamic sciences and provided an important influence on the intellectual revival of Italy. Spain under the Mayyads and their successors developed into the most important source of learning to western scholars of the late middle ages.

Greek scientific tradition survived to a certain degree in Byzantium and experienced a final renaissance under the influence of Persian and Arabic works in the period of restoration between the sacking of Constantinople by the Venetians and the crusaders (1204) and the fall of the city in 1453 under the Turkish onslaught. Islamic science flourished for the last time under Mongol rulers particularly at the court of Ulugh Beg (d. 1449), the grandson of Timur (Tamerlane). At the same time Europe took the lead, beginning with the Italian Renaissance, which rapidly transformed the inherited methods to what were to become the foundations of modern science.

Simple categories are no longer applicable to the modern development of mathematics, though the earliest phase naturally followed closely the examples of antiquity. The development of analysis (Fermat, Descartes, Newton) soon left behind the classical methods and problems, and an enormous wealth of new discoveries revealed an interaction between theoretical mathematics and all branches of physics and astronomy. This period of often somewhat uncontrolled discovery culminated in the work of Leonard Euler (1707–1783). Soon afterward the need for increasing rigor and abstraction became the dominant motif which remained characteristic for mathematics thereafter. This tendency not only profoundly influenced each of the traditional branches of mathematics; it likewise all but obliterated the boundaries between individual fields by uncovering their common logical and

operational background. By the second half of the 20th century the enormous importance of mathematical physics, accompanied by the development of high-speed computing machines, furnished a new incentive to mathematical research similar to the situation at the threshold of the 19th century.

ANCIENT AND MEDIEVAL

Mesopotamia.—The superiority of Babylonian mathematics is based on the place-value notation of its number system which was equally well adapted to the expression of numbers, however large, or of fractions. This system is not the result of some intentional invention but emerged slowly during the 3rd millennium B.C. In the highly developed economic life of this period, a notation for the recording of monetary transactions originated in which larger and smaller units of weights of silver were expressed by simple juxtaposition of numbers, denoting units of different values, similar to the notation \$5.20 as distinguished from \$20.5. Thus the arrangement of the numbers determined their relative value; in our example the ratio of dollars to cents is 1 to 100, in the Babylonian monetary system it happened to be 1 to 60. This notation was then extended to numbers in general, so that one ended up with a "sexagesimal place-value system." In our example 5.20 means $5 + \frac{20}{60} = 5 + \frac{1}{3}$ (dollars) or $500 + 20 = 520$ (cents). Similarly $2,30$ in the sexagesimal system means $2 + \frac{30}{60} = 2 + \frac{1}{2}$ or $2 \times 60 + 30 = 150$. All other arithmetical rules familiar to us from the decimal system have their exact counterpart in the sexagesimal place-value system. We know by heart all products of integers up to 10 times 10. The Babylonians (and later the Greek and Arabic astronomers) tabulated the corresponding products up to 60 times 60. In this fashion all arithmetical operations, additions, subtractions, squares, cubes and square roots and cube roots, multiplications and divisions, were carried out first in Babylonian mathematics from the 2nd millennium B.C. on and then—beginning around the 5th century B.C.—by the astronomers of Mesopotamia, of Greece and Alexandria, of India, of the Islamic world and the Byzantines and their western pupils to the 15th century A.D. and later.

A number system which is based on a place-value notation encounters the problem of the occurrence of empty places; e.g., in the sexagesimal system, this is the case when in an addition some digits total exactly 60 which then are carried as 1 to the next higher place. In the earlier period of Babylonian mathematics one had no special symbol for such cases and had carefully to watch the relative order of the digits. In the late period, however, a special sign was written for every empty place. This "zero" symbol was in common use in all astronomical computations and reached the Hellenistic mathematicians, along with the sexagesimal place-value notation. Thus in all Greek trigonometric tables, e.g., in Ptolemy's *Almagest* (about A.D. 140), a zero sign is used exactly as we would use it. The same holds for Islamic and Byzantine tables; in these late Greek manuscripts the form 0 for zero is the most common one. When Hindu astronomy was developed under western influence, beginning about the 5th century A.D., the zero symbol was transferred to a decimal place-value notation. This decimal system was well known to Islamic scholars, although the astronomical practice remained sexagesimal in most cases. In western Europe, the decimal notation gained ground very slowly and it was not until the 17th century that a consistent decimal place-value notation was developed by François Vieta (1540–1603) and Simon Stevin (1548–1620).

The facility of numerical computations, as the result of a place-value notation, is everywhere visible in Babylonian mathematics. An Old Babylonian text (written about 1700 B.C.) investigates, for example, triples of "Pythagorean" numbers; i.e., numbers which satisfy the relation $a^2 + b^2 = c^2$. Many problems were of the following type: find two numbers of given sum when also their difference, or their product, or their quotient is known. The first and the third problems are solvable linearly; the second can be reduced to the first by squaring the sum and subtracting four times the product. The resulting procedure is the normal form for the solution of quadratic equations in Babylonian mathematics. On the basis of this insight a numerical algebra was

developed leading to the determination of unknown quantities from a system of linear relations, or from very elaborate quadratic equations, or equations of fourth order obtained by squaring second degree expressions. Similar problems in geometric formulation were handled (division of fields, etc.) involving the concept of similarity, the basic area relations, volumes, etc. In purely numerical respects, one went on to tables of consecutive powers of certain integers and to special cases of the inverse problem, analogous to determining the logarithm of a number. Also problems of compound interest occur. This does not exclude the study of purely geometric relations. The "Pythagorean" theorem for right triangles, the fact that a triangle inscribed in a semicircle is a right triangle, relations in regular polygons, etc., were known, leading to very good approximations of $\sqrt{2}$, $\sqrt{3}$, etc. For π the crude value 3 was often used, but $3\frac{1}{8}$ also was known. (See also PYTHAGORAS AND PYTHAGOREANISM.)

Egypt.—The main sources of our knowledge of Egyptian mathematics are two papyri, the so-called Rhind (or Ahmes) papyrus of the British museum (written about 1650 B.C.) and the Golenishev papyrus in Moscow (from about 1900 B.C.). Several smaller fragments confirm the impressions gathered from the two larger texts. The arithmetical operations were developed on an additive basis, repeated duplication for multiplication, with corresponding rules for division and fractions, derived from successive halvings. These often long-winded procedures were used to solve very elementary practical problems; e.g., distributing in given quotas bread and beer. In the same numerical fashion were determined areas of triangular or polygonal fields, volumes of solids, in particular of a truncated pyramid (probably in the special shape of a corner block of two sloping walls). The area of a circle was found by squaring $1-\frac{1}{8}$ or $\frac{8}{9}$ of the diameter (corresponding to a value of about 3.16 for π). The oft-repeated assertion attributing to the Egyptians a knowledge of the formula for the sum of a geometric progression is based on a modern misinterpretation.

Greek and Hellenistic Mathematics.—Late antiquity attempted to supplement the dim records of the past by associating the origin of mathematical knowledge with the early philosophical schools of the 7th and 6th centuries B.C. in Ionia (Thales) and southern Italy (Pythagoras). These claims are not confirmed by modern research. The basic facts of elementary geometry and arithmetic had for many centuries been known in Mesopotamia. On the other hand, Greek astronomical and cosmogonic concepts in the 5th century B.C. (e.g., Philolaus) are still so primitive that only a very narrow margin is left for earlier discoveries. Indeed, it seems more plausible to assume that the independent development of Greek mathematics began essentially in the time from which we have the first reliable records; namely, the determination of certain areas bounded by circular arcs by Hippocrates of Chios (second half of the 5th century), and the investigation of curves in space in connection with the problem of the duplication of the volume of a cube by Archytas of Tarentum (first half of the 4th century). Whether this rapid development of scientific mathematical theory had anything to do with the increasing contact with the near east is unknown, but, offhand, it seems not very likely. Clear influence of the oriental tradition appears much later in the writings of Hero (1st century A.D.) and Diophantus (period uncertain) although the numerical methods of astronomy reveal Babylonian influence at least since Hipparchus (c. 150 B.C.).

Although Plato's lifetime (c. 428–c. 348 B.C.) belonged to the most important formative period of Greek mathematics, it seems unlikely that any active role in the development was played by him. Nevertheless, philosophy was of great importance for the origin of scientific mathematics, if only for the necessity of removing mathematical argumentation from the unsafe ground of philosophical discussion. The paradoxes about the infinite divisibility of space and time (Zeno of Elea, 5th century B.C.) and the related attempts of avoiding them through the assumption of atomistic structures (Democritus, c. 400 B.C.) led to the necessity of defining exactly the postulates to be made for the objects of mathematical discussion. These investigations soon resulted in the discovery that the rational numbers do not suffice for the

measurement of geometrical quantities and thus require an independent foundation of geometry. Thus the mathematicians of the early 4th century B.C., foremost among whom were Theaetetus (d. 369 B.C.) and Eudoxus, developed a geometric theory of what we now call the irrational numbers. Similarly, the concept of area gave rise to a rigorous theory of integration.

The strictly geometric formulation of these problems directed Greek mathematics away from algebraic procedures, although a purely algebraic notation had been used by Aristotle (384–322 B.C.) in his investigation of formal logic, in spite of the continuation of the oriental tradition within elementary mathematics. Numerical and even graphical methods were used to a large extent within theoretical astronomy as we know from Ptolemy's *Almagest* and his minor writings, but nowhere is there visible an approach to the concept of "function," which is of such fundamental importance for the development of modern mathematics. Consequently all problems which lead to integrations are attacked as individual geometric problems since it was unknown that integration is the inverse process of finding the derivative. Similarly, the problem of finding tangents to curves, e.g., conic sections, is never seen from the viewpoint of functional relationship.

As mentioned before, theoretical mathematics perhaps received its original impetus from such philosophical problems as the meaning of infinite divisibility of lines, the meaning of area and volume, or the mutual relationship between geometrical and arithmetical ratios, the latter connected with the theory of harmonies. But from a relatively early period on, two other lines of interest are also discernible; namely, curves traceable by mechanical means and conic sections. To the first group we count the problems of spherical geometry as suggested by the apparent motion of the celestial bodies. Also the second group probably has an astronomical origin; namely, the theory of sun dials. By the end of the 4th century all these areas of investigation had reached a level at which a certain codification became possible or even necessary. Eudemus, a pupil of Aristotle, wrote a history of mathematics—unfortunately it is known to us only by some short excerpts. Somewhat later appeared Euclid's *Elements* concerning the most refined part of theoretical mathematics, culminating in Book x, the classification of irrationals. A work on conic sections by Euclid is lost but some smaller writings have survived, notably a spherical astronomy which shows how far one still was from a spherical geometry. This is confirmed by a treatise of Aristarchus of Samos (first half of 3rd century B.C.), who clearly did not yet have standard trigonometrical procedures at his disposal.

The theory of conic sections, however, had in the meantime reached a high degree of perfection and its significance for the solution of algebraic problems had been understood. This was amply attested by the use of conic sections made by Archimedes and, above all, by the great work of Apollonius (c. 200 B.C.). In the latter we find a systematic discussion of elementary properties of axes, chords, tangents, asymptotes, focal properties, conjugate directions, etc. But many theorems are also proved, the significance of which was recognized only with the development of projective geometry. Thus we find, for example, the relationship between harmonic quadruples utilized for the proof that five points (or three points and one tangent or one point and two tangents) determine a conic section. We find theorems of duality, transformation of co-ordinates, a discussion of evolutes and theorems which are related to the projective generation of conic sections from pencils of lines.

With Archimedes and Apollonius, theoretical mathematics had reached its climax in antiquity. From then on, astronomical problems determined the direction of further progress (see *ASTRONOMY: History of Astronomy*). Apollonius showed that the anomalies in the motion of sun, moon and planets can be explained as either eccentric or epicyclic motion. It is easy to see that the apparent position of a body moving on an eccentric circle can be predicted by simple trigonometric relations which, in turn, are always reducible to the solution of right triangles. The new element brought to the problem by its astronomical application consists in the need for repetitiveness, in order to describe the motion of a body by its consecutive positions. This leads to

the construction of numerical tables or to graphical or mechanical devices. In the 3rd century B.C., Babylonian mathematical astronomy had reached full maturity. With Hypsicles and Hipparchus, the Babylonian numerical methods, with difference sequences as the main tool, appeared in Greek astronomy. Hipparchus is credited with the computation of a table of chords. In the same period must belong the invention of stereographic projection which transfers problems of spherical geometry to plane geometry under preservation of circles. Similarly, methods of descriptive geometry were invented, the so-called analemma, again with the purpose of treating spherical problems in the plane. This phase of the development was completed by the middle of the 1st or the end of the 2nd century B.C.

The progress of spherical trigonometry was much slower, for obvious reasons. Plane trigonometry involves no new principle beyond the Pythagorean theorem and the fact that two chords over a diameter form a right angle—both known since Old Babylonian times. Spherical trigonometry required entirely new insight, in particular the restriction to great circle arcs. The discovery of the latter fact seemed to be due to Menelaus (c. A.D. 100) and it was especially remarkable because astronomical experience suggests very strongly the consideration of parallel circles. The contrast between the work of Menelaus and the earlier *Spherics* of Theodosius (1st century B.C.) shows clearly the progress made. Inequalities and qualitative considerations were replaced by accurate solutions of spherical triangles, based on the Menelaus theorem. With Ptolemy (2nd century A.D.) this method became the standard procedure for spherical astronomy.

In the 4th century A.D., the sciences became an object of teaching and commentaries. Pappus, Theon of Alexandria and Hypatia paraphrased, commented on and edited the great classics. We owe much to their industry, and a work like the *Mathematical Collection* of Pappus had great influence on the revival of mathematics in the 17th century, particularly on Descartes. The philosopher Proclus (5th century) wrote an introduction to the *Almagest* and commented on Book I of Euclid's *Elements*. Eutocius (6th century) still competently discussed Archimedean treatises. But what was left of Greek mathematical literature in Byzantium had sunk to the level of elementary summaries.

The Middle Ages.—Very few details are known about the survival of ancient science during the period from the final victory of Christianity to the beginning of Islamic science in the 9th century. Persia undoubtedly played a role in this process, not only as a refuge for exiles—non-Christian as well as Christian—from orthodox persecution, but also as an intermediary with India. In the 6th century, under Sasanian rule, Jundi-Shapur (southwestern Iran, Khuzistan province) was a centre of learning, particularly in medicine, and the same city provided the Nestorian physician of the Abbasid caliph al-Mansur. Under this ruler's influence a project of systematic translating was begun, centred at the "House of Wisdom" in Baghdad and based on a widespread search for Greek scientific literature. In the same period, Indian astronomy had reached Baghdad, thus creating the first school of Islamic astronomy, the best-known representative of which is al-Khwarizmi (d. about 850). His name still lives in our "algorithm" as well as in "algebra," which was derived from the title of one of his works, *Kitab al-jabr wa'l muqabala*, famous although of little originality since it closely follows the tradition of elementary mathematics which we can trace from Mesopotamia through the works of Hero and others. Yet, for the revival of mathematics and astronomy, al-Khwarizmi's work was of great importance.

The most significant contribution of India to medieval mathematics was the replacement of the Greek chord function by sine function (though multiplied by constant factors; e.g., 3438' in order to obtain a circumference of 360° for the circle). The use of the decimal system, however, remained of much lesser importance though it occurred occasionally in Islamic, and then also in Byzantine, works. No influence on the west was exerted by the development in India of a theory of Diophantine equations, beginning in the 6th century A.D. (Aryabhata) and ending in the 12th (Bhaskara). The origin for these investigations in all probability lay in questions related to the periodicity of planetary phenomena.

Thus methods had been known in India that were not rediscovered until Bachet de Mézirac (1624) in Europe. The Hellenistic theory of numbers culminated in Euclid's proof of the existence of an infinity of prime numbers and of the Euclidean algorithm. What remained of Greek theory of numbers, for example in Iamblichus (A.D. 300) or Diophantus (date unknown but sometimes placed A.D. 200–300), did not form a connected theory and had little influence during the middle ages.

The progress due to Islamic mathematicians and astronomers probably lay mostly in the perfection of computational devices. Accurate tables for the sin- and tan-function were computed, and methods were devised to modify particularly the first-mentioned function in order to tabulate the equation of centre for planetary orbits. Spherical trigonometry was developed far beyond the level reached in antiquity. The use of the Menelaus theorem was replaced by more elegant methods; e.g., the sin-theorem, known since about A.D. 1000 (Abul Wefa). At the same time the ancient tradition of descriptive geometry and graphical procedures was developed in the theory of sun dials.

Abul Wefa and his contemporary Kushyar bin Labban wrote treatises on sexagesimal computation. From them proceeds a continuous tradition to al-Kashi, the first director of Ulugh Beg's observatory in Samarkand (about 1400). Among these scholars, the so-called Ruffini-Horner (1804–1819) method was developed for the determination of the n th root by means of an iteration process. Al-Kashi wrote a treatise on the computation of π in which he gives approximations both in sexagesimal and decimal fractions to 9 and 16 places, respectively, based on the comparison of an inscribed and a circumscribed regular polygon of more than 800,000,000 sides.

It is natural to measure Islamic science by its new discoveries and independent achievements. It is clear that the five centuries from A.D. 900 to 1400 cannot compete with the most creative period of Hellenistic science from 300 B.C. to A.D. 200. One must read such masterpieces of scientific analysis as al-Biruni's work on India (1030) or Ibn Khaldun's (1332–1406) sociological studies in order to understand the depth of Islamic cultures which westerners rightly regarded with the greatest of admiration.

The process of transmission of Islamic science to Europe began in the 11th century with men like Adelard of Bath who visited Syria or Leonardo Pisano in north Africa and Italy at the time of Frederick II, whose court in Palermo became a centre of learning. Gerard of Cremona (c. 1114–1187), working in Toledo, was perhaps the most prolific translator of Arabic versions of Greek works (Euclid, Archimedes, Theodosius, etc.). Only a long series of names would cover the European scholars who worked in Spain during the 12th and 13th centuries, often helped by Jewish scholars, in their efforts to commit to Latin an Arabic text. Their works formed the foundation on which the science of the Renaissance was built.

(O. E. N.; X.)

MODERN PERIOD

In 1545, only two years after Copernicus had published his *De revolutionibus* and Vesalius had corrected the physiology of Galen. Geronimo Cardano published the *Ars magna*, a book that opened a new era in mathematics. Linear and quadratic equations had been solved for thousands of years, but the cubic had resisted all efforts until suddenly several Italian algebraists discovered a solution. First to succeed seems to have been Scipione del Ferro (c. 1510); but the formula often is named for Niccolo Tartaglia, a rediscoverer, or for Cardano, who first published it in the *Ars magna*, together with Lodovico Ferrari's solution of the quartic. This unexpected success gave a fillip to the theory of equations, and enthusiasm for "the great art" (algebra) spread to other lands. Simon Stevin of Bruges gave rules for locating roots of equations and established the systematic use of decimal fractions (1585). In France, at the court of Henry IV, François Vieta gave algebra a new name (the "analytic art") and a more general form. His use of vowels for unknown quantities and consonants for known paved the way later for the important concepts of variable and parameter, as well as for the rapid rise of a truly symbolic algebra. He is remembered also for his part (1579) in continuing the efforts of

Johann Müller (Regiomontanus) (1464) to establish trigonometry as more than a stepchild of astronomy.

17th Century.—Vieta died in 1603, just over the threshold of the "century of genius." Brilliant discoveries were about to crowd close upon each other. In 1614 John Napier published his discovery of logarithms; and the following year Johannes Kepler devised infinitesimal methods which Bonaventura Cavalieri in 1635 fashioned into a geometry of indivisibles. In 1637 René Descartes published, along with his *Discours de la méthode*, his greatest discovery—analytic geometry. Co-ordinates, the analytic method, graphical representation of functions and the application of algebra to geometry were not new at that time; but Descartes (and also his contemporary, Pierre de Fermat) correlated these in the basic principle that an equation in two unknown quantities represents a curve and vice versa. The ancient synthetic geometry of static figures now had a powerful and dynamic rival in the algebraic geometry of variable magnitudes.

In fact, except for isolated instances (such as the projective geometry of Gérard Desargues and Blaise Pascal in 1639), "Cartesian geometry" completely overshadowed "pure geometry" for almost two centuries. One of the immediate results of the new geometry was a tremendous increase in the variety of curves which came to be studied. So few curves previously had been known that no need had been felt for a general definition of tangent line; a tangent had been, with certain obvious exceptions, a line which touches the curve at one and only one point. It was Fermat, primarily, who introduced the modern idea of the tangent to a curve at a given point P . In essence, he took a second point Q on the curve, found the slope of the secant line PQ , and from this, by permitting Q to tend toward coincidence with P , he calculated the slope of the tangent. This method rightly earned for him the title of inventor of the differential calculus. When one notes also his share, together with Pascal, in the founding of the theory of probability (1654), his work on the quadrature of curves, his use of mathematical induction and his achievements in the theory of numbers, one appreciates why Fermat, for whom mathematics was but an avocation, has been hailed as the greatest of amateurs. Fermat found the length of the semicubical parabola in 1658, the year in which Christiaan Huygens determined the length of the cycloid—although rectifications had been anticipated by Evangelista Torricelli, student of Galileo, who had found the length of the logarithmic spiral (c. 1640). Pascal and John Wallis also studied the cycloid, a curve whose beautiful properties led to so many disputes over priority that it has been dubbed the "Helen of geometry." Huygens showed that the evolute of a cycloid is an equal cycloid, a property which led to the concept of curvature and which he applied in making pendulum clocks.

Development of the Calculus—Newton and Leibniz.—Of all the mathematicians of the 17th century, none compared in power and original contributions with Sir Isaac Newton. One of his earliest discoveries was that of the binomial theorem for rational fractional exponents. The binomial formula introduced Newton to infinite series, a topic which loomed large in his invention of the calculus at about the same time (1666). Areas by integration had been found, through summations, by earlier mathematicians from Archimedes to Wallis; and differentiations had been carried out by Fermat. It remained for Newton and Gottfried Leibniz to discover the fundamental principle of the calculus—that integrations can be performed far more easily by inverting the process of differentiation. This capital discovery was made possible, in the case of Newton, by his study of the methods of his teacher, Isaac Barrow, as well as by works of Fermat and Wallis; Leibniz seems to have been led to the calculus independently (c. 1673–76) by reading the works of Barrow and Pascal. Neither inventor was able to establish the calculus on a sound logical basis. Newton at first adopted a crude explanation in terms of infinitely small "moments"; later he had recourse to the plausible but undefined idea of "prime and ultimate ratios" of the rates of change (fluxions) of flowing quantities (fluents). Leibniz tried (unsuccessfully) to explain his method in terms of sums and quotients of infinitely small "differentials," the notation for which was so felicitous that it has been used ever since.

Newton's first publication of the calculus was in 1687 in a short scholium in the *Philosophiæ naturalis principia mathematica*, conceded to be the greatest of all scientific treatises. The *Principia* is couched in the synthetic language of the ancients, even though the discoveries in the book were made through the new analytic devices which the author helped to develop. Newton is best known for his demonstration, in the *Principia*, of one of the greatest of scientific generalizations, the law of gravitation. Newton's discovery of the composite nature of white light was published in the *Opticks* of 1704, a treatise containing also Newton's *Quadrature of Curves* and his *Enumeration of Cubic Curves*. Where Newton's aim was to understand nature, the motive of Leibniz was to find a general pathway to knowledge. The Leibnizian search for a universal characteristic, which resulted in the first steps toward symbolic logic, failed to attract a following until the publication of George Boole's *Laws of Thought* (1854); but the method of differentials, the formal algorithmic nature of which was in accord with the aims of its inventor, became the mainspring of mathematical development in the following century.

18th Century.—The mathematical contributions of the versatile Leibniz were more modest than those of Newton, but their influence on the continent was far greater. The Bernoulli family in particular, great admirers of Leibniz, were fired with enthusiasm for the differential calculus; and the greatest and most influential pupil of Jean Bernoulli was Leonhard Euler, the most prolific mathematical author of all time. The 18th century saw few spectacular discoveries; yet this prosy age generated more new mathematics than had any earlier period—and most of this centred about the work of Euler. One of his treatises, the *Introductio in analysin infinitorum* of 1748, may be called the foremost mathematical textbook of modern times, for it fashioned the function concept and infinite processes into the third member of the mathematical triumvirate comprising geometry, algebra and analysis. The *Introductio* contains the earliest algorithmic treatment of logarithms as exponents and of the trigonometric functions as numerical ratios; in it the five proper quadrics are first recognized as members of a single family; and the book systematized the use of parametric equations, polar co-ordinates and the graphical representation of elementary functions.

Euler contributed to all analytic aspects of mathematics. His treatises on the differential and integral calculus are the source from which modern authors have drawn material; he was one of the founders of the calculus of variations and of differential geometry; he was the greatest figure in the theory of numbers since Fermat; and he contributed much to mathematical physics. The vast scope of his interests accounted perhaps for a lack of soundness in logical foundations. He based the calculus on quotients of "qualitative zeros," and he had no qualms about operating with the "sums" of divergent series.

Mathematicians of the 18th century generally were connected with a university or a royal court, and Euler, no exception, found patrons at Berlin and St. Petersburg. When in 1766 Euler resigned from the Prussian academy to return to Russia, Frederick the Great chose as his successor J. L. Lagrange, reputed the greatest mathematician of the century. The interests of Lagrange (algebra, analysis, the theory of numbers and mechanics) were much like those of Euler, but his disposition was different. Lagrange published far less, but his contributions were beautifully finished products with a sound foundation. His *Théorie des fonctions analytiques* of 1797 made mathematicians more keenly aware of the need for rigour; but the book which earned him greatest fame was the *Mécanique analytique* (1788), which established mechanics as a branch of mathematical analysis. Beginning with a small number of postulates, such as the principle of "virtual work," the author built up the principles of the subject without recourse to anything beyond deductive logic. The Age of Reason, typified by the mathematician and encyclopaedist Jean le Rond d'Alembert, may be thought of as culminating in Lagrange's *Mécanique*, published just one year before the opening of the French Revolution. The greatest legacy left to mathematics by the French Revolutionary period was the establishment in 1795 of the École Polytechnique, a school which boasted among its teachers the

greatest mathematicians of France, including Lagrange, Pierre Simon Laplace and Gaspard Monge. Laplace established celestial mechanics as a branch of analysis, and it was through his work that such tools as potential theory, the "Laplace transform," the "Laplace equation" and orthogonal functions became the stock in trade of the analyst. His masterpiece, the *Mécanique céleste* (5 vol., 1799–1825), purported to prove the stability of the solar system, for the origin of which the author proposed the nebular hypothesis. The students of the École Polytechnique esteemed as their greatest teacher Gaspard Monge, who began an era in mathematics characterized by a resurgence of geometry. The *Géométrie descriptive* (1799) of Monge, originally devised for military purposes, was the first significant contribution to synthetic geometry after 1639; but the author was not a single-minded synthesist, and the emphasis at the École Polytechnique upon analytic and differential geometry was in large measure the result of the successful textbook of Monge (1795). The key idea in his work was that each step in an analytic calculation corresponds to some geometrical construction. Lazare N. M. Carnot, the "organizer of victory" for the French revolutionary armies, likewise contributed both to analytic and synthetic geometry, his greatest treatise being the *Géométrie de position* (1803), although he is better known for his theorems on transversals.

19th and 20th Centuries.—Carnot had sought to avert the despotism of Napoleon, but Monge and J. B. J. Fourier were friends and ardent admirers of the emperor. Fourier's chief contribution to mathematics is typical of the originality (but not the rigour) of the new century. His classic *Théorie analytique de la chaleur* (1822) showed that an arbitrary function can be expanded in a "Fourier series" of sines and cosines. In the very same year, Fourier's boldness in analysis was paralleled in projective geometry by the *Traité des propriétés projectives des figures* of J. V. Poncelet, a student of Monge. Poncelet became a centre of controversy over the "principle of continuity" and the idea of duality. His reckless charges of plagiarism antagonized a young German geometer, Julius Plücker, who turned from synthetic methods to become the greatest of analytic geometers.

In his many treatises, Plücker developed the ideas of abridged notation, homogeneous co-ordinates (of points, lines and planes), enumerative geometry and the line as an element in a four-dimensional space. In Germany his work was not well received, for Jakob Steiner by 1832 had built up a strong following in synthetic geometry. Steiner hated analysis as thoroughly as Lagrange disliked geometry, arguing that calculation replaces thinking, whereas pure geometry stimulates it. His ideas were carried on (1847) by K. G. C. von Staudt, who, with still sharper logic, examined the structure of pure geometry.

Non-Euclidean Geometry.—Probably no earlier period in the history of mathematics rivaled the 19th century either in critical spirit or in originality of development, both of which are seen in the rise of non-Euclidean geometry. Attempts to prove the parallel postulate had been so numerous as to constitute a "fourth classical problem of antiquity"—until N. I. Lobachevski (1826–29) and Johann Bolyai (1831–32) showed that it is possible to build self-consistent geometries in which this postulate is denied. In 1854 G. F. B. Riemann proposed the characterization of a geometry by the quadratic differential form for arc length, an idea essential later in general relativity. C. F. Gauss, still another independent discoverer of non-Euclidean geometry, failed to publish his thoughts on the subject. The informed consensus is that Archimedes, Newton and Gauss were the greatest mathematicians of all time. When he was not yet 19, Gauss discovered (1796) that a regular polygon of 17 sides can be constructed in the Euclidean sense. Other results (non-Euclidean geometry, the graphical representation of complex numbers, the double periodicity of elliptic functions) were entered in his diary and went unpublished until rediscovered by others. His *Disquisitiones arithmeticae* (1801), containing the law of quadratic reciprocity and the algorithm of congruences, is a classic in the theory of numbers; and the *Disquisitiones generales circa superficies curvas* (1828) marked a new epoch in differential geometry through the exploitation of the parametric representation of surfaces and their "Gaussian curvature." These books show a

modern tinge in the meticulous attention to proofs. Gauss was also a prolific contributor to statistics (including the method of least squares, invented independently by A. M. Legendre) and to applied mathematics (especially in astronomy, geodesy and magnetism).

Theories of Groups, Functions and Complex Variables.—Gauss proved (1799) that every polynomial equation has at least one complex root, but it remained for two younger contemporaries, N. H. Abel and Évariste Galois, independently to demonstrate that in most cases the root cannot be expressed by means of radicals. Abel's proof (1824) that the quintic cannot be "solved" led Galois to seek general criteria of solvability. Galois (who died in 1832, before his 21st birthday) observed that every algebraic equation is associated with a certain group of substitutions and that solvability is determined by the properties of this group, thus establishing the "Galois theory" or the theory of groups. In 1872 Felix Klein, in his famous *Erlanger Programm*, pointed out the unifying role of the group concept in geometry; and Sophus Lie, through the theory of continuous groups (about 1873), made it a part of analysis. Gauss and A. L. Cauchy, the foremost mathematicians of their day, are typical exponents of 19th-century mathematics in their rigour and inventiveness. The prolific Cauchy was the successor of Lagrange in the theory of functions, to which subject he added the theory of a complex variable. The graphical representation of complex numbers by J. R. Argand (1813–14) and the discovery by Abel (1824) of the imaginary period of elliptic functions had led up to this; but the complex variable really came into its own in 1825 with the "Cauchy integral theorem." This work later was continued in two directions: Karl Weierstrass emphasized the pure analytic aspect through the "analytic continuation" of functions defined by power series; Riemann made greater use of geometric intuition through a study of conformal representation and "Riemann surfaces."

Algebraic Geometry.—British mathematics had been handicapped throughout the 18th century by excessive deference to synthetic methods and the notations of Newton. In 1816, however, the Cambridge Analytical society was formed to promote the Leibnizian methods of the calculus. Moreover, the first half of the 19th century was characterized by the rise of mathematical journals (mathematical societies being chiefly a product of the latter half of the same century), and these facilitated publication and dissemination of knowledge (see MATHEMATICS, SOCIETIES OF). Hence it was not long before England, through the voluminous work of Arthur Cayley, became the stronghold of algebraic geometry. The geometry of n dimensions had been hinted at by Sir William Hamilton (1843) and Hermann Grassmann (1844), but Cayley is regarded as the true founder of this branch of geometry (1869), as well as of the theory of matrices and algebraic invariants. Algebra, overshadowed by analysis for two centuries, again was assuming a decisive role, with the application of determinants in algebra and analysis becoming one of the most fruitful lines of development. The critical spirit of the 19th century found clearest expression in the ever-greater arithmetization of mathematics. Bernard Bolzano already had taken a step in this direction in 1817 by giving an analytic proof of the location theorem; but development of the foundations of arithmetic dates especially from 1872 when definitions of irrational number were given by Weierstrass. Julius Dedekind and Georg Cantor. These definitions, based on the notion of infinite classes, led Cantor (in his *Mengenlehre* of 1895–97) to one of the most strikingly original contributions of all time—the theory of transfinite numbers. After showing that the class of algebraic numbers is denumerable, Cantor was led to the startling conclusion that the "number" of points in space of n dimensions is not greater than that in a single dimension, a paradox confirmed by the Peano space-filling curve.

Influence of Science on Analysis.—Perhaps the most powerful impetus on the development of analysis came from mathematical physics and astronomy (see ANALYSIS). The common role of extremal principles for the laws of optics as well as dynamics became clear through the work of Sir William Rowan Hamilton (1824–37) and Karl Gustav Jacobi (1837–43). The geometric interpretation of the $2n$ "canonic variables" of the dynamic dif-

ferential equations led Sophus Lie (about 1873) to the concept of contact transformations and continuous groups which, in its abstract form, gained an important place in modern topology. The deep interaction between analysis and mathematical physics is also visible in the work of the almost self-taught genius James Clerk Maxwell, which ranges from the investigation of the stability of Saturn's rings to thermodynamics and his celebrated field theory of electrodynamics (1873). The theory of statistical mechanics as developed by Maxwell, Ludwig Boltzmann and J. Willard Gibbs opened the road to the investigation of the so-called ergodic theorems (solution by George David Birkhoff, 1932). Through the theory of probability by A. Kolmogorov and A. Khintchine (1932) it had become clear that problems of statistical mechanics are essentially problems of the theory of measure, and in this form the ergodic theory has again developed into a branch of abstract mathematics. A similar development can be observed in the theory of integral equations which slowly emerged during the second half of the 19th century from problems of electrostatics and the theory of potentials. The essential turn toward a solution originated from the investigation of determinants of infinitely many rows and columns, begun by G. W. Hill (1877) in connection with the perturbation theory of the lunar motion. This new type of approach led Erik Fredholm (1900) to the discovery of the algebraic analogue of the theory of integral equations, which was crowned by the theory of eigen-values of David Hilbert (1906) and the related theory of spaces of infinitely many dimensions ("Hilbert space" and its modern generalizations).

Fundamental Questions.—Hilbert in 1900 prophetically proposed to the second International Congress of Mathematicians at Paris a series of fundamental problems which should challenge the efforts of the new century. The first problems concerned the continuum, where the question of whether or not there is a transfinite number between that of a denumerable set and that of the continuum remained unanswered. Questions inquiring about the transcendence of certain numbers were partially solved by C. L. Siegel (about 1930) and by Gelfond's theorem, although results here still were sporadic. The problems which stimulated the most spectacular development were those lying in the relatively novel field of analysis situs or topology. Certain puzzle problems of Euler were suggestive of topology, and Gauss prophesied the rise of the new subject, but the origins are more clearly apparent in results of Henri Poincaré (1890–1904). By the middle of the 20th century the infant prodigy had burgeoned into a major branch of mathematics. Originally an offshoot of geometry, topology became closely related also to algebra and analysis.

One of Hilbert's favourite questions concerned the compatibility of the axioms of arithmetic. Gottlob Frege in 1879 had given a critical definition of the word "number," and just a decade later the Peano postulates for arithmetic were proposed; but by far the most ambitious effort to establish the foundations of mathematics appeared in the *Principia Mathematica* (3 vol., 1910–13) of Bertrand Russell and A. N. Whitehead. This *Principia*, like that of Newton, set the fashion for decades to come, so that research in symbolic logic at mid-20th century constituted a major branch of mathematics. In fact, the greatly expanded role of the axiomatic approach became possibly the most conspicuous aspect of 20th-century mathematics. Such studies in the foundations of mathematics engendered lively controversy in which varying orthodoxies are distinguishable—from the formalists, who assert, as did Hilbert, that mathematics is a meaningless game played with meaningless symbols, to the intuitionists, who, with L. E. J. Brouwer, hold to a more Kantian view of the "inner meaning" of the subject. One of the factors contributing to the dilemma was the persistence of deep-rooted paradoxes. By rejecting the use of impredicative definition, Poincaré, Hermann Weyl, and Brouwer were able to eliminate the antinomies; but this drastic solution, to which Brouwer (and later Weyl) added also the rejection of the law of excluded middle, cut the ground out from under much of classical mathematics. Hilbert sought to save the mathematical fortunes by rejecting the idea of mathematics as necessarily "true," clinging only to the criterion of self-consistency; but such efforts were dealt a shattering blow by Goedel's theorem. Kurt

Goedel in 1931 showed essentially that if the game of mathematics actually is consistent, the fact of this consistency cannot be proved within the rules of the game itself (see MATHEMATICS, FOUNDATIONS OF).

The conclusion which necessarily follows from such a devastating discovery is that the ultimate foundations of mathematics remain a deep mystery—at least to mathematicians. One should expect the result of this to be a deep pessimism. On the contrary, one found everywhere in the modern period the faith that mathematics was entering a golden age surpassing even the brightest periods of the past. Theories of integration, revolutionized by H. L. Lebesgue through his concept of measure (1902), had carried the subject far beyond Archimedes, Cauchy and Riemann into the realm of abstract spaces; and the unification of analytic methods had led to the general analyses of E. H. Moore (1906) and Maurice Fréchet (1928).

The atmosphere of 20th-century algebra, with its concern for such abstract axiomatic concepts as field, ring and ideal, was far more general than that of any previous age. Geometry—now encompassing spaces of infinitely many dimensions—undertook a critical examination of its postulational basis.

MATHEMATICS, SOCIETIES OF. Mathematicians have always felt the need to communicate their results and problems to their colleagues. Until the 17th century these needs were met by personal contact and correspondence and by the publication of books. Thereafter there grew a multitude of societies devoted to mathematical knowledge, with an even greater number of periodical publications.

The oldest mathematical society still in existence in the 1960s is the Mathematische Gesellschaft in Hamburg, Ger., founded in 1690 as the Kunstrechnungsliebende Societät, and continued (1790–1876) as the Gesellschaft zur Verbreitung der Mathematischen Wissenschaften. Its publications were entitled *Jahresbriefe* or *Jahres-Berichte* or *Berichte* (1723–1878) and *Mitteilungen* (1873–80, mimeographed; 1881 et seq., printed).

Another early organization was the Mathematical society founded as a discussion circle in Spitalfields, London, in 1717. It continued until 1845, when it was absorbed by the Royal Astronomical society.

Most national mathematical societies did not appear until the

second half of the 19th century, the scientific academies and the independent mathematical periodicals having sufficed until then. One exception is the Wiskundig Genootschap, founded at Amsterdam in 1778.

The oldest of the major national societies is the Moskovskoe Matematicheskoe Obshchestvo (Moscow Mathematical society), organized in 1864 as a circle for mathematics enthusiasts and re-established on a wider basis in 1867. It publishes the important periodical *Matematicheskii sbornik* (*Recueil Mathématique*; 1866 *et seq.*) and *Trudy Moskovskogo Matematicheskogo Obshchestva* ("Transactions of the Moscow Mathematical society"; 1952 *et seq.*). There are many other mathematical societies in the U.S.S.R., that at Kharkov having been established in 1879.

The London Mathematical society, founded in 1865, began as a purely local society in London, most of the original members being at University college; its first president was Augustus De Morgan. It grew rapidly, however, and soon established itself as the national mathematical society of England. It publishes *Proceedings* (1865 *et seq.*) and a *Journal* (1926 *et seq.*), the latter containing shorter papers. The Edinburgh Mathematical society was founded in 1883 and publishes *Proceedings* (1883 *et seq.*) and *Mathematical Notes* (1909 *et seq.*).

The Société Mathématique de France was founded in 1872, its first president being Michel Chasles. It publishes a *Bulletin* (1872 *et seq.*).

The New York Mathematical society, founded in 1888, became the American Mathematical society in 1894. With more than 5,700 members, it is one of the most important mathematical societies in the world; and its meetings are held in all parts of the United States. Its periodical publications include the *Bulletin* (1891 *et seq.*), containing reports of lectures, abstracts of papers presented to the society, records of the society's activities and book reviews; *Transactions* (1900 *et seq.*) for longer papers; *Memoirs* (1950 *et seq.*) for papers of unusually great length; and *Proceedings* (1950 *et seq.*) for short papers (before 1950 the *Bulletin* was used for short papers also).

The Deutsche Mathematiker-Vereinigung, founded in 1890, is the German national society. Its *Jahresbericht* (1892 *et seq.*) contains many extremely valuable expository surveys of mathematical progress.

In Italy the Circolo Matematico di Palermo, founded in 1884, achieved international status; its *Rendiconti* (1887 *et seq.*) was for many years one of the most important mathematical periodicals in the world. The Unione Matematica Italiana was established in 1922; it publishes a *Bollettino* (1922 *et seq.*).

By the 1960s national mathematical societies had been formed in most countries; two of the most important outside Europe and the Americas were the Indian Mathematical society, which began in 1907 as a local club in Madras, and the Mathematical Society of Japan, which was formed after World War II as a partial continuation of the earlier Physico-Mathematical Society of Japan (founded 1884). Each publishes a journal. See also ACADEMIES.

Occasional international meetings of mathematicians took place during the 19th century, but the first of the present series of international congresses of mathematicians was held in 1897. The congress has met regularly every four years after 1900, except for interruptions caused by World Wars I and II. The *Proceedings* of each congress have been published, usually by the mathematical society of the sponsoring country. After World War I an abortive attempt was made to establish a permanent International Mathematical union; the project was revived in 1950 and a new union was formed; it was admitted to the International Council of Scientific Unions in 1952.

BIBLIOGRAPHY.—F. Klein, *Vorlesungen über die Entwicklung der Mathematik im 19. Jahrhundert*, 2 vol. (1926–27); *World List of Scientific Periodicals*, 3rd ed. (1952); N. G. Parke, *Guide to the Literature of Mathematics and Physics* . . . , 2nd rev. ed. (1958); H. A. Steeves, *Russian Journals in Mathematics, Survey and Checklist* (1961); T. L. Yüan, *Bibliography of Chinese Mathematics, 1918–1960* (1963). The list of abbreviations of names of journals at the end of the index numbers of *Mathematical Reviews* gives a rather complete list of periodicals containing papers of mathematical interest.

(F. Ss.; J. V. W.; X.)

MATHER, COTTON (1663–1728), American Congrega-

tional minister and author, the most celebrated of all American Puritans although an extreme example, rather than typical, of the tradition for which he stood. He lived all his life in Boston, where he was born Feb. 12, 1663, the son of Increase Mather and grandson of John Cotton and Richard Mather (*qq.v.*). He took his A.B. at Harvard in 1678, his A.M. in 1681, was made a fellow in 1690 and joined his father in the ministry of the Second church in 1685.

The prominence of Mather's ancestry, combined with a profound mystical strain, led him throughout his life to believe that he was destined to accomplish great deeds in continuation and perhaps fulfillment of the work which the first colonists had begun. But his heritage worked against him also, for to many of his contemporaries he was the embodiment of an outdated ideology. He saw his political influence dwindle as the Brattle Street church, which advocated a broad basis for church membership, was founded (1698) and prospered; his father was ousted from the presidency of Harvard in 1701, which led him to resign his fellowship in 1703; and Joseph Dudley became governor in 1702. He did not relent in the zeal with which he opposed men and institutions which he believed to be derogations from the primitive purity of Massachusetts, but his tremendous energy came more and more to be channeled into his ministry and the production of nearly 450 separate printed works.

One of Mather's chief concerns was the presence of the supernatural in daily life, and he collected instances of this in his *Memorable Providences Relating to Witchcraft and Possessions* (1689). He is, therefore, generally credited with stimulating the frenzy which culminated in the witchcraft trials of 1692. Although he believed in the presence of witches and was determined to counteract witchcraft, Mather did not generalize about the trials, but weighed each case on its own merits, believing that some had been sentenced unjustly and cautioning the judges to be scrupulous in their acceptance of evidence.

Mather produced sermons and works of scriptural explanation, scientific instruction and political morality. His most famous and valuable work is his biographical and historical collection, *Magnalia Christi Americana* (1702), which contains information about almost every significant man or deed from the founding of New England to his time. He rarely allowed any successful experiment of his to remain unpublished if he felt the information would make for a better life and, therefore, he produced numerous tracts on subjects as diverse as the christianizing of Negroes and the raising of children.

Interest in science, which at one time encouraged Mather to consider a career in medicine, furnished him with a wide European correspondence on natural and supernatural phenomena in America. This resulted in his being elected to the Royal society in 1713 and is reflected in his *Curiosa Americana* (1712–24). He was an enthusiastic leader in the campaign for inoculation against smallpox in 1721, even though popular disapproval resulted on one occasion in a bomb's being thrown into his house. His impressive scholarship and tireless writing gained him an honorary degree from the University of Glasgow in 1710, an award which he especially cherished because of his differences with Harvard. These differences led him to take an interest in the new college in Connecticut, to urge Elihu Yale to contribute to it and to suggest to Gov. Gurdon Saltonstall that the college be named for Yale. Mather appears to have been offered the Yale presidency in 1721.

Mather died on Feb. 13, 1728. He was married three times and had 15 children, only two of whom survived him. He was nervously sensitive and frequently hot-tempered, both of which qualities increased his alienation from the popular trends of his day, such as the antitheocratic political movement and the establishment of heterodox Puritan and Anglican congregations in Boston. Nevertheless, he wielded a strong personal influence, and Benjamin Franklin remembered him with warmth, attributing his own penchant for practical schemes to notions derived from Mather's essays. Mather was the first American minister to organize clubs for young people, and he initiated the practice of regular calls upon aged and ailing parishioners and upon prisoners, as well as making himself available to any who summoned him.

Although his writings are saturated with archaisms and learned allusions, he was a conscious literary stylist and achieved passages of literary merit. His written work and his activities reflected his constant zeal for the betterment of his fellows and his sincere devotion to the ideal which he believed was responsible for the settlement of America and indispensable for its success.

Sibley, *Biographical Sketches of Harvard Graduates*, vol. iii (1873-85), and *Literary History of the United States*, vol. iii (1949) and Supplement (1959). K. B. Murdock (ed.), *Selections From Cotton Mather* (1926), contains a biographical and critical introduction; Perry Miller, *The New England Mind: From Colony to Province* (1953), considers Mather in the context of his time. Numerous short articles on Mather's life and activities appear in the *Proceedings of the American Antiquarian Society* and of the *Massachusetts Historical Society*; and in *Publications*, Colonial Society of Massachusetts. (L. Z.)

MATHER, INCREASE (1639-1723), American Congregational minister, author and statesman, a determining influence in the councils of New England during the crucial period when leadership passed into the hands of the first native-born generation, was born in Dorchester, Mass., on June 21, 1639, the oldest son of Richard Mather (q.v.). He graduated from Harvard in 1656, took his M.A. degree at Trinity college, Dublin, in 1658 and ministered to various congregations in England. He returned to Boston in 1661, married Maria, daughter of the Rev. John Cotton (q.v.), in 1662, and became the father of Cotton Mather (q.v.) in 1663. He became teacher of the Second church of Boston in 1664, licensor of the press in 1674, fellow of Harvard in 1675 and in 1685 president of the college. The last office he lost in 1701, in great part as a consequence of political opposition to his stand on the Massachusetts charter. When, in 1683, Charles II demanded that Massachusetts surrender the original charter by which the citizens elected their own governor, Mather took the lead in opposing the order. He perpetuated the theocratic ideal of the founders by pronouncing compliance with the royal demand to be a sin. After the charter was vacated by the court of chancery in 1686, Mather remained in the forefront of the opposition, hindering the measures of the royal governor, Sir Edmund Andros.

In 1688 Mather was sent to London as the emissary of some of the Massachusetts churches to try to regain the old colonial charter, and in 1690 he was made one of the colony's official agents in England. He stayed in London until 1692, interviewing James II, William III, Queen Mary and many others influential in politics. He enlisted in his cause the good offices not only of his Puritan brethren but also of the Quaker William Penn and of the Anglican bishops Burnet and Tillotson. When prospects of full restoration of the old charter appeared hopeless, Mather turned his energies to procuring measures favourable to the colonists in the new charter of 1691, and so succeeded as to be allowed to nominate the royal governor and other officers for the first year under that charter. Sir William Phips, the governor of his choice, proved unpopular, as did the charter itself, so that those who longed for the liberties of the old charter refused to concede that its restoration had been an impossibility and held Mather responsible for the new restrictions.

After leaving the presidency of Harvard, Mather was less active in public affairs, but he wrote much and remained a dominating figure in Congregational councils. He published more than 150 books, most of them theological, but a few dealing with history, biography or, in part, with science. Among the more interesting are his life of Richard Mather (1670), his political tracts written in 1688-93, his *Essay for the Recording of Illustrious Providences* (1684), a collection of narratives of strange happenings in New England with discussion of a few scientific topics, his *Brief History of the Warr With the Indians* (1676) and his account of the Indian wars in New England, *A Relation of the Troubles . . .* (1677). His *Cases of Conscience* (1693) displays his attitude toward the witchcraft trials. Mather died on Aug. 23, 1723.

Harvard developed during Mather's term of office; his agency in England had important historical results; and to the fame given him by these things was added that derived from his reputation as a preacher and scholar. He manifested his interest in science

by forming a scientific society in Boston in 1683. His large library reflected the wide range of his reading in politics, science, the classics and history, as well as in theology. His hot temper, his stout championing of his own doctrine—though he was more moderate in debate than most of his adversaries—and his reputed ambition made enemies, who, however, were always outnumbered at home and abroad by those who revered him as a leader. He combined leadership in both church and state with greater effect than had any other Massachusetts minister since the settlement of the colony, and is regarded as the greatest of the native American Puritans.

Murdock, *Increase Mather, the Foremost American Puritan*, detailed biography with a list of Mather's writings and sources of information about him (1925); Cotton Mather, *Parental Tutor* (1724); W. Walker, *Ten New England Leaders* (1901); J. L. Sibley, *Biographical Sketches of Harvard Graduates*, vol. i (1873-85). For a study of Mather's time: Perry Miller, *The New England Mind: From Colony to Province* (1953). Likenesses of Mather are reproduced and discussed in K. B. Murdock, *The Portraits of Increase Mather* (1924). (L. Z.)

MATHER, RICHARD (1596-1669), American Congregational minister, was born in Lowton, Lancashire, Eng. At 15 he began to teach at a grammar school at Toxteth Park, near Liverpool. In 1618 he attended Brasenose college, Oxford, for a few months, but in November became minister of the Toxteth chapel. His Puritan tendencies led the ecclesiastical authorities to silence him in 1634, and on Aug. 17 of the next year he arrived at Boston, Mass. A year later he became teacher of the church at Dorchester, Mass., and held that office until his death on April 22, 1669.

Mather was locally celebrated as a preacher, and his books on the principles of New England Congregationalism together with his activity in colonial church councils made him one of the most famous New England Puritans of his day. He was one of the translators of *The Whole Booke of Psalmes* (1640), the "Bay Psalm Book" designed for use in colonial churches. His greatest achievement was a statement of the creed and polity of Massachusetts Congregationalism which, with but few alterations, was printed as *A Platform of Church Discipline* (1649). This, the "Cambridge Platform," was for years the basic document of his sect in Massachusetts. He was an active advocate of the "Half-Way Covenant," a plan which provided a modified form of church membership for those who were unable to meet the tests prescribed by the original Congregational polity.

By his first wife, Katharine Holt of Bury, whom he married in 1624, he had six sons, four of whom became ministers; the eldest was Increase Mather, father of Cotton Mather (q.v.). His second wife was Sarah Cotton, widow of the Rev. John Cotton of Boston.

Richard Mather* (1670), reprinted with Richard Mather's journal of his voyage to New England (1850); Cotton Mather, *Magnalia*, book iii, pt. 2, ch. 20 (1702); W. Walker, *Ten New England Leaders* (1901); K. B. Murdock, *Increase Mather*, ch. 1-4 (1925). (K. B. M.)

MATHEWS, CHARLES (1776-1835), English actor with a wonderful gift of mimicry, was born in London on June 28, 1776. His father was "a serious bookseller" who also officiated as minister in one of Lady Huntingdon's chapels. Mathews was educated at Merchant Taylors' school. He first appeared on the stage in Dublin in 1794, and his London debut took place in 1803 at the Haymarket theatre in the roles of Jabal in *The Jew* and of Lingo in *The Agreeable Surprise*. From this time his professional career was an uninterrupted triumph. Mathews visited the United States in 1822 and 1834; his last appearance in New York city was made on Feb. 11, 1835, when he played Samuel Coddle in *Married Life* and Andrew Steward in *The Lone House*. In 1797 Mathews had married Eliza Kirkham Strong (d. 1802) and in 1803 Anne Jackson, an actress, author of the popular and diverting *Memoirs*, by Mrs. Mathews (4 vol., 1838-39). He died at Plymouth on June 28, 1835.

His son CHARLES JAMES MATHEWS (1803-1878) was born in Liverpool on Dec. 26, 1803, educated at Merchant Taylors' school and then articulated to an architect. He went on the stage, appearing at the Olympic theatre, London, in 1835 as George Rattleton in his own play *The Humpbacked Lover*. In 1838 he married

Madame Vestris (*q.v.*), then lessee of the Olympic. Their joint management of this and other theatres, including Covent Garden and the Lyceum, failed. Mathews visited the United States in 1838. As an actor, he held in England an unrivaled place in his own peculiar vein of light, eccentric comedy. His wife died in 1856, and Mathews visited the United States again in 1858 and married Mrs. A. H. Davenport. He was one of the few English actors who played in French successfully and was acclaimed in Paris in 1863. At the age of 65 he made a world tour, appearing again in the United States. Returning to England in 1872, he continued to act until his death on June 24, 1878. His last appearance in New York was at Wallack's theatre on June 7, 1872, and in London at the Opéra Comique on June 2, 1877. His last stage appearance was at Stalybridge, Cheshire, in 1878.

See Charles Dickens (ed.), *Life of Charles James Mathews*, 2 vol. (1879); H. G. Paine, *Actors and Actresses of Great Britain and the United States* (1886).

MATHEWS, SHAILER (1863–1941), U.S. educator and theologian, one of the leaders in the Social Gospel movement of the late 19th and early 20th centuries, was born in Portland, Me., on May 26, 1863, and educated at Colby college, Waterville, Me., Newton Theological institution, Newton, Mass., and the University of Berlin. From 1884 to 1894 he taught at Colby. He occupied various professorial posts in the divinity school of The University of Chicago until his retirement in 1933, when he became dean emeritus. During his tenure as dean of the divinity school (1908–33) he was constantly engaged in academic research, public lecturing, editorial responsibilities and a host of ecclesiastical, political and social activities. He held a number of high ecclesiastical and professional offices and contributed significantly to the reorganization of theological education in the United States. Mathews published more than a score of books and hundreds of articles. His major publications include *The Messianic Hope in the New Testament* (1905); *The Spiritual Interpretation of History* (1916); *The Faith of Modernism* (1924); and *Creative Christianity* (1935). His autobiography, *New Faith for Old* (1936), is a significant document for the history of the Social Gospel movement in the United States. He died in Chicago on Oct. 23, 1941.

(W. H. A.)

MATHEWSON, CHRISTY (CHRISTOPHER) (1880–1925), famous U.S. baseball player also known as "Matty" and "Big Six." A National league pitcher, his most outstanding achievement came in the world series of 1905 when he shut out the Philadelphia Athletics in three games. Born on Aug. 12, 1880, at Factoryville, Pa., he was one of the first of five baseball immortals voted into the National Baseball Hall of Fame at Cooperstown, N.Y., in 1936. He was one of the first college men to enter the major leagues, having been a baseball and football player at Bucknell university, Lewisburg, Pa. A right-handed thrower and batter, he pitched for the New York Giants from 1900 to 1916 and the Cincinnati Reds in 1916; he also was used in the outfield and at first base for New York. He won 372 games in his career and was the master of the fadeaway pitch, later known as the screwball (see *BASEBALL: Pitching*). Noted as a control pitcher, Mathewson established an all-time league record of 2,499 strike-outs, and a season mark of 267 strike-outs, in 1903. He won 30 or more games in four separate seasons and 20 or more games in nine other years. He pitched a no-hit, no-run game (*v.* St. Louis) on July 15, 1901. He was manager of the Cincinnati club from 1916 to 1918 and served as president of the Boston Braves from 1923 to 1925. He died of tuberculosis at Saranac Lake, N.Y., on Oct. 7, 1925.

(D. SR.)

MATHURA (formerly *MUTTRA*), a city and district located in the Agra division of Uttar Pradesh, India. The city, headquarters of the district, lies about 80 mi. S.S.E. of Delhi, on the right bank of the Jumna (Yamuna) river. Pop. (1961) 125,258 (comprising the municipal area 116,959 and the cantonment 8,299). In the 6th century B.C. it was the capital of the Saurasenas. Fa-hsien (*c.* A.D. 400), the Chinese traveler, refers to it as a Buddhist centre, but Hsüan Tsang (*c.* 650) recorded a Brahmanical revival. Mahmud of Ghazni sacked it in 1017–18. Sultan Sikandar Lodi (about 1500), Shah Jahan (1636) and Aurangzeb (1669–70) caused the

destruction of the Hindu shrines and temples. It was again plundered by Ahmad Shah in 1757. The city is still a great centre of Hindu devotion. Temples and ghats (bathing stairs), mostly modern, line the river bank. Two degree-granting colleges and a state college of veterinary science and animal husbandry are affiliated to Agra university; Curzon archaeological museum is in Dampier park. Printed cotton cloth and pilgrims' charms are the chief manufactures. The town is a rail and road junction.

MATHURA DISTRICT (area 1,467 sq.mi.; pop. [1961] 1,071,279) lies on both sides of the Jumna which divides it into two parts. The smaller eastern part consists of a rich upland plain irrigated by the branches of the Ganges (Ganga) canal. The western portion, less fertile, is watered by the Agra canal. The principal crops are wheat, sugar cane, pulses, millets, barley and cotton.

The central part is revered in Hindu mythology. Braj-Mandal, as the area within a sacred circuit of 170 mi. round Gokul and Vrindaban (Brindaban) was called, is rich in legends of Krishna (*q.v.*) as relics in towns of Mathura, Gobardhan, Gokul, Mahaban, Vrindaban, Baldeo, Barsana and Radha Khund attest. After the invasion of Mahmud of Ghazni, the area fell into insignificance till the reign of Akbar; thenceforward its history merges with that of the Jats of Bharatpur, until it again acquired separate identity under Suraj Mal in the mid-18th century. It passed under British rule in 1804.

(S. S. BH.)

MATILDA (sometimes called the EMPRESS MAUD) (1102–1167), consort of the Holy Roman emperor Henry V and afterward claimant to the English throne in the reign of King Stephen, was the only daughter of Henry I by Queen Matilda. She was born in London in 1102, sister of William the Aetheling. Both her marriages were in furtherance of Henry I's policy of strengthening Normandy against France. In 1114 she was married to Henry V; he died in 1125, leaving her childless, and three years later she was married to Geoffrey Plantagenet, effectively count of Anjou. Her brother's death on the "White Ship" in 1120 made her Henry I's sole legitimate heir, and in 1127 he compelled the Anglo-Norman baronage to accept her as his successor, though a woman ruler was equally unprecedented for kingdom and for duchy. The Angevin marriage was unpopular and flouted the barons' stipulation that she should not be married out of England without their consent. The birth of her eldest son, Henry, in 1133 gave hope of silencing this opposition, but he was only two when Henry I died (1135) and a rapid coup brought to the English throne Stephen (*q.v.*) of Blois, son of William the Conqueror's daughter Adela. Though the church and the majority of the baronage supported Stephen, Matilda's claims were powerfully upheld in England by her half brother Robert of Gloucester (*q.v.*) and her uncle King David I of Scotland. Matilda and Robert landed at Arundel in Sept. 1139, and she was for a short while besieged in the castle. But Stephen soon allowed her to join her brother who had gone to the west country, where she had much support; after a stay at Bristol she settled at Gloucester.

She came nearest to success in the summer of 1141, after Stephen had been captured at Lincoln in February. Elected "lady of the English" by a clerical council at Winchester in April, she entered London in June, but her arrogance and tactless demands for money provoked the citizens to chase her away to Oxford before she could be crowned. Her forces were routed at Winchester in Sept. 1141, and thereafter she maintained a steadily weakening resistance in the west country. Her well-known escape from Oxford castle over the frozen river took place in Dec. 1142. Normandy had been in her husband's possession since 1144, and she retired there in 1148, remaining near Rouen to watch over the interests of her eldest son, who became duke of Normandy in 1150 and king of England in 1154. In 1155 she dissuaded him from attempting the conquest of Ireland. She spent the remainder of her life in Normandy exercising a steady influence over Henry II's continental dominions. She died on Sept. 10, 1167. As a young woman she had not been unpopular in Germany, and it is possible that the chroniclers are unfairly critical of her conduct in England in the 1140s, where her cause inspired the outstanding loyalty of Robert of Gloucester, Miles, earl of Hereford, and Brian Fitz-Count.

G. W. S. B.

MATILDA (c. 1046–1115), countess or margravine of Tuscany, remembered for her role in the conflict between the papacy and the German kings or Holy Roman emperors, was a member of the house of Canossa (q.v.). Her great-grandfather Atto Adalbert (d. 988) had acquired the counties of Modena, Reggio and Mantua; her grandfather Tedald had added those of Brescia and Ferrara. In 1027 her father, Boniface, was invested by the German king Conrad II with the march of Tuscany, with which he combined his extensive possessions north of the Apennines. The house of Canossa had been traditionally loyal to the German kings; but after his marriage (soon after 1036) to Beatrice, daughter of Duke Frederick II of Upper Lorraine, Boniface began to oppose Conrad's son, Henry III. He was assassinated in 1052; and on the death, soon afterward, of his elder daughter Beatrice and of his son Frederick, Matilda remained his only surviving child and became, on her mother's death in 1076, the sole heiress of his dominions. In 1054, meanwhile, her mother had married Godfrey the Bearded, who because of his opposition to Henry III had been deprived of the duchy of Upper Lorraine. Since Godfrey was suspect to him, Henry in 1055 took Beatrice and Matilda in custody to Germany; but after Henry's death in 1056, they returned to Tuscany together with Godfrey, whose power was now uncontested and whose brother Frederick became pope in 1057 (Stephen X or IX; d. 1058). Godfrey the Bearded, who became duke of Lower Lorraine in 1065, died in 1069. In the same year his stepdaughter Matilda was married to his son Godfrey the Hunchback (d. 1076).

Matilda's character and religious development were deeply influenced by her confessor and counselor, Bishop Anselm II of Lucca, and by her friend Pope Gregory VII. Throughout the Investiture conflict (see GERMANY: History; INVESTITURE CONTROVERSY) she supported Gregory with undaunted determination, first together with her mother and then alone, though Godfrey the Hunchback had taken Henry IV's side. Matilda's castle of Canossa was the scene of Henry IV's penance before Gregory VII (Jan. 1077). During the renewed struggle after Henry's second excommunication in 1080, Henry deposed Matilda and deprived her of her possessions (1081). Lucca, Siena and other Tuscan towns, as well as many Tuscan counts and bishops, deserted her. Yet she continued to maintain the papal cause after Gregory VII's death (1085); and in 1089, doubtless for political reasons, she married the 17-year-old Welf V (Welf II as duke of Bavaria from 1101), from whom she was separated a few years later. In 1093 she urged Henry IV's son Conrad to rebel against his father and to assume the Italian crown. In 1110 she finally concluded peace with Henry V; and in the following year she made him the heir of her allodial possessions, though she had already made a donation of them to the papacy—probably in 1080—and had renewed this donation in 1102. This was to give rise to endless controversies between papacy and empire. She died at Bondeno near Mantua on July 24, 1115, and was buried in the abbey of St. Benedict at Polirone. Pope Urban VIII had her remains taken to Rome and reinterred in St. Peter's (1634).

BIBLIOGRAPHY.—The principal, though not always reliable, source for the life of Matilda is the contemporary *Vita Mathildis* by Otto von Donizo, a monk at Canossa; there is an edition by L. Bethmann in *Monumenta Germaniae Historica, series Scriptores*, vol. xii (1856). Other sources are the lives of Anselm of Lucca by Bardo and by Rangerius, in *M.G.H. Scriptores*, vol. xii and xxx, part 2 (1934); and A. Falce (ed.), "Documenti inediti dei duchi e marchesi di Toscana . . ." in *Archivio storico italiano*, 86 (1928). See A. Overmann, *Gräfin Mathilde von Tuscien, ihre Besitzungen. Geschichte ihres Gutes von 1115–1230 und ihre Regesten* (1895); R. Davidson, *Geschichte von Florenz*, vol. 1 (1896); N. Grimaldi, *La Contessa Matilde e la sua stirpe feudale* (1928). (N. R.)

MATINS (MATTINS), the breviary office for the night, originally intended to be said at midnight but sometimes said at dawn. In the modern Roman Catholic Church, outside monastic services, the office is usually said on the preceding afternoon or evening. In the Church of England the term matins is used for the service of morning prayer. See BREVIARY; HOURS, CANONICAL.

MATISSE, HENRI EMILE BENOÎT (1869–1954), considered by many to be the most important French painter of the

20th century, was born at Le Cateau, Nord, on Dec. 31, 1869. He started studying law, but at the age of 20 took up painting while recovering from an illness. He studied first under the popular Adolphe Bouguereau but, finding him too academic, soon moved to the greater freedom of Gustave Moreau's studio. There he remained for five years, studying and copying the old masters in the Louvre. Matisse could have followed this profitable path but when he discovered the great Impressionist painters, especially Camille Pissarro, his whole outlook radically changed, and in 1897 he exhibited his first successful original picture, the large "Dinner Table" (Niarchos collection). Matisse then threw himself into the stream of the most advanced art and, although forced to live on a pittance, joined the *avant-garde* painters, André Derain, Georges Rouault and Maurice de Vlaminck. In 1901 he exhibited at the Salon des Indépendants, and Berthe Weill showed several of his canvases in her small gallery. In 1904 the most influential dealer in Paris, Ambroise Vollard, gave him a one-man show and also bought the "Dinner Table." Matisse was then launched, but it was not until the next year that he became a public sensation when he exhibited an astounding and brilliant portrait of his wife, "Woman With the Hat" (Hass collection, San Francisco, Calif.), at the famous 1905 Salon des Indépendants. Matisse and his friends had unleashed colour so riotously that they were dubbed the *Fauves* or "wild beasts," and visitors to the "central cage," the gallery where their pictures were hung, howled and jeered. It was an American, Leo Stein, brother of Gertrude Stein, who had the courage to buy the "Woman With the Hat."

In 1906 Matisse painted the first of a long series of masterpieces, "Joy of Life" (Barnes foundation, Merion, Pa.). A visit to Morocco gave him a new insight into colour; a trip to Italy, where he saw Giotto and the Siennese, a new vision of line; while an exhibition of Islamic art in Munich introduced him to the vivid and intricate designs of the east. Matisse then executed three of the most important paintings of his career, for the famous Russian collector Sergei Shchukin: "Harmony in Red" (1908) and the two decorative panels for the staircase of his Moscow palace, "Dance" and "Music" (1910). Shchukin's large collection of Matisse's was acquired by the Hermitage museum, Leningrad.

For the next seven years Matisse produced at least one masterpiece a year: "The Red Studio" (1911; Museum of Modern Art, New York city), "Moorish Cafe" (1912–13; Hermitage), "Mme. Matisse" (1913; Hermitage), "Mlle. Landsberg" (1914; Philadelphia), "The Moroccans" (1916; Museum of Modern Art) and in 1917, perhaps Matisse's greatest year, "Piano Lesson" (Museum of Modern Art), "Music Lesson" (Barnes foundation) and the triptych "Three Sisters" (Barnes foundation). The first Matisse in the U.S. were shown by Alfred Stieglitz in 1908 at his "291" gallery, New York city. In the Armory show (1913) Matisse had 13 paintings.

After such an amazing output of important canvases with their invention and daring distortion, Matisse went to live in Nice,

BY COURTESY OF THE MUSEUM OF MODERN ART, CITY OF NEW YORK AND MR. SAMUEL A. BARNES
"THE MOROCCANS," HENRI MATISSE, 1916. OIL ON CANVAS. IN THE MUSEUM OF MODERN ART, NEW YORK

France, where the Mediterranean atmosphere proved a relaxation, reflected especially in his brilliant paintings of Moorish odalisques. During this period between World Wars I and II his pictures ceased to astonish the *avant-garde*, but their daring colour delighted an ever-increasing group of purchasers. After a short trip to Tahiti he executed an important mural (1932-33) for the Barnes foundation. During World War II Matisse had a new burst of creative energy, and even in his 80th year produced paintings such as "Egyptian Curtain" (Phillips gallery, Washington, D.C.) and "Large Interior in Red" (Musée Nationale d'Art Moderne, Paris), both reminiscent of his finest period.

Throughout his life Matisse produced considerable sculpture, many lithographs and etchings, and illustrated numerous books, notably *Poésies de Stéphane Mallarmé* (1932). He also designed the settings for two important ballets: *The Nightingale* (1920) for Diaghilev, and *Rouge et Noir* (1939).

In 1943 Matisse retired to Vence, a small village in the hills behind Nice. There he designed the entire decoration of the Chapel of the Rosary for the Dominican nuns (1948-51). His work included the brilliant stained-glass windows, furniture, vestments and mural paintings on white tiles with strikingly original stations of the cross. This chapel, visited by thousands of tourists yearly, was described by Matisse himself as his masterpiece. He died in Nice on Nov. 3, 1954.

MATLOCK, an urban district and vacation resort of Derbyshire, Eng., is 18 mi. N. of Derby by road. Pop. (1961) 18,505. The district, of beautiful valleys and rugged hills on the southeastern side of the Peak National park, comprises a group of towns and villages extending about nine miles along the river Derwent. Between Cromford (where Sir Richard Arkwright used his first water-powered mill in 1771) and Matlock Bridge (16th century) the river runs through a narrow gorge dominated by the High Tor on one side and the wooded slopes of Masson hill on the other.

Chatsworth house, the home of the duke of Devonshire, and Haddon hall, a residence of the duke of Rutland, lie just outside the district boundary. The hydropathic treatment for which Matlock was once famed is no longer available. The largest hydro, Smedley's, is now the county offices, and the Matlock Training college occupies Rockside and Chatsworth hydros. At Matlock Bath the thermal water (20° C. or 68° F.) is no longer used for medicinal purposes but serves an open-air swimming pool, the fishponds and "petrifying" wells. There are a number of limestone caves. The Roman "Nestor" lead mine is part of the Rutland cavern in the wooded Heights of Abraham. Industries include agriculture, horticulture, quarrying and mining (limestone, gritstone, lead and fluorspar), textiles and grain milling. (J. O. Hu.)

MATO GROSSO, a state in the west-central region of Brazil, bounded north by Amazonas and Pará, east by Goiás and Minas Gerais, southwest by São Paulo and Paraná, northwest by Rondônia and Bolivia and southwest by Paraguay. Area 475,501 sq.mi. Pop. (1960) 910,262. Most of Mato Grosso lies on the Brazilian plateau and marks the watershed which separates the Amazon basin from the basin of the Plata river system. The western section of the state, chiefly a flood plain (*pantanal*), is among Brazil's best grazing lands. In the southeast is the valley of the Paraná, along the east the valley of the Araguaia, and to the north the tableland descends to the basin of the Amazon. Elevations range from 300 to 400 ft. in the lowlands to 3,000 ft. on the plateau. Natural vegetation consists mainly of patches of scrub growth and light forest. The annual average rainfall is 50-60 in. with a distinct dry season from May to September.

Livestock raising and agriculture represent the principal economic activities of Mato Grosso, which is one of the great frontier regions of the world. The state supports more than 6,000,000 head of cattle, many being driven to market in São Paulo each year. The state is known to have important deposits of gold, diamonds, iron, manganese and platinum. The inadequacy of transportation facilities is a major barrier to further development.

Mato Grosso's 4,000 mi. of roads are largely trails, many of which are impassable during the rainy season. Paved roads are seldom found outside the limits of the principal cities of Cuiabá (pop. [1960] 43,112), the state capital, Corumbá (36,744) and Campo Grande (64,477).

Cuiabá (*q.v.*) has not attained the economic importance of Corumbá (*q.v.*) or Campo Grande in modern times because of its isolation. Campo Grande and Corumbá are served by the Brazilian Northwest railroad, which provides access to Santos and Rio de Janeiro. Coast-to-coast travel is possible via the Corumbá-Santa Cruz (Bolivia) railroad.

Campo Grande is the main agricultural centre in southern Mato Grosso, a position enhanced by the railroad communication with São Paulo, the movement of the coffee frontier toward the west and northwest of São Paulo state, and the concomitant shift of population. The existence of *terra roxa* and other fertile soils in the Campo Grande region and south into Dourados allows a wide diversity of crops to be grown. Coffee, rice, cotton, sugar cane and corn, the main commercial crops, are produced in that order. Colonization projects have been instituted by the federal and state governments in the Dourados region, with emphasis upon coffee cultivation.

Mato Grosso ("great woods") was settled first by pioneering Paulistas after they had been forced to retreat from Minas Gerais by the so-called war of the *emboabas* in 1709, over mining rights in the gold fields. The state was initially a district of the captaincy of São Paulo with the founding of Cuiabá in 1719, and in 1748 it became an independent captaincy. Mato Grosso became a province of the empire in 1822 and a state of the federal union in 1889. While sections of the state remained unexplored in the 1960s, the expedition of Marshal Candido Mariano Rondon in the early part of the 20th century furnished the first complete, accurate data about Mato Grosso. (J. L. Tr.)

MATRIARCHY, a theoretical human social system in which final authority would reside in women. Tales are still told of villages where only women lived, maintained by the annual admission of one male who was killed when his procreative task was done. However, the consensus among modern anthropologists and sociologists is that no reliable evidence (either contemporary or historical) supports the theory. See MATRILINITY; BACHOFEN, JOHANN JAKOB.

MATRILINITY means matrilineal descent; i.e., descent group membership gained through the mother. Patriline indicates that descent group membership is gained through the father. If either form operates exclusively in a given society the system is known as unilineal descent. When matrilineal and patrilineal descent groups operate simultaneously in the same society, the rule of descent is called double unilineal.

Matriliney is not matriarchy; in matriarchy women hold ultimate authority over the family, household, community or state. Matrilineal descent, matrilineal residence and a complex of other related customs were supposed to be associated with a system in which women hold the reins. Whether such a state of affairs preceded or followed patriarchy (its logical counterpart) in social evolution was hotly debated in the 1900s; but the debate has stilled. No peoples on earth are known to be organized matriarchically, nor are there reliable historical records of such societies. If there ever were matriarchates in the very earliest times, there is no trustworthy evidence for their existence. In the light of established data, there exists no single, indivisible complex that can be called a matriarchy; particularly, the empirical absence of the crucial element of matriarchy (ultimate authority in the hands of women) strips the term of its relevance. (See BACHOFEN, JOHANN JAKOB.)

It is important to distinguish the descent rule from such social rules as those governing inheritance, succession, residence and the locus of formal authority over descent group activities. Whether the group is matrilineal or patrilineal, formal authority over descent group activities is found (if at all) in the hands of men. Although in some cases queens may rule with almost absolute power, the society as a whole has never been found in which women in general have authority over men in general. Formal authority in a patrilineal group resides in the husband, father, father's brother

and father's father. The authority in a matrilineal lineage is in the hands of men who are brothers, mother's brothers, mother's mother's brothers and so forth.

Inheritance and succession refer to the transmission of property and office (such as chieftainship) after the death of the holder. These may follow the matrilineal line, as in the nepotic rule under which a man inherits from or succeeds his mother's brother. Among Trobriand Islanders a man may inherit his mother's brother's magic (*see* MAGIC, PRIMITIVE) or he may succeed to his mother's brother's chiefly office. On the other hand, patrilineal inheritance and succession may occur, or chiefly office may be elective or appointive without regard to descent even though matrilineal descent groups are present in the society.

Similarly, the rules of residence for the newly wedded couple may be matrilocal, in which case the couple lives with the matrilineal kinsmen of the bride; avunculocal, when the couple live with the matrilineal kinsmen of the groom (*see* AVUNCULATE); and patrilocal, where they live with the patrilineal kinsmen of the groom. The Hopi (*q.v.*) Indians of Arizona have matrilineal clans and follow the rule of matrilocal residence. In the Trobriand Islands, the rule of avunculocal residence is followed, as it is on Losap, an atoll of the east Caroline group in Micronesia. On Yap, in the West Caroline Islands, where matrilineal clans occur alongside patrilineal lineages, residence is patrilocal.

There is no necessary and inevitable correlation between matrilineality and any particular rule of inheritance, succession, residence or authority; nevertheless certain rules tend to occur together in logically and functionally consistent clusters. Thus, of all the rules of residence the matrilocal and avunculocal rules are (in a sense) the most consistent with the rule of matrilineal descent. According to D. F. Aberle (1961) about half of all matrilineal societies are also matrilocal, while about one quarter of them have avunculocal residence; the rest follow other rules.

Descent groups differ in terms of the particular combination of social rules under which they are organized. Matrilineal and patrilineal descent groups might be thought of as precise mirror images of each other in the essential features of their structure. However, empirically they have important structural differences, largely since specific males (as husbands, fathers and father's fathers) hold formal authority over the patrilineal group, while under matrilineality other males (as brothers, mother's brothers and mother's mother's brothers) have such authority. This means that no known descent group, matrilineal or patrilineal, is matripotestal; *i.e.*, there are no matriarchates.

Patrilineal and matrilineal descent groups are similar in that males hold authority in both. But, since the line of affiliation (the descent line) runs through women only in matrilineal groups, there is a crucial structural difference. It means that patrilineal descent groups depend on females neither for continuity of the descent line nor for authority functions, while matrilineal groups depend on males for authority and on females for continuity. Under matrilineality there is an interdependence of the sexes which is not replicated under patrilineality; this fundamental difference gives rise to others. For example, there are few (if any) matrilineal groups in which marriage is as stable as it is among some patrilineal groups. Under matrilineality there is a structured conflict between a woman's husband and her brothers over control of the woman and her children; this is not replicated in patrilineal groups. Further, the processes of group fission, segmentation, growth and expansion are different.

Although matrilineal descent is widespread, patrilineality is about twice as frequent. Matrilineal systems are quite rare in the east Eurasian and Mediterranean areas, but are well-represented in Africa, the Americas and in Oceania. Matrilineal descent is not often found among peoples who make their living by herding large animals, nor among those who depend heavily on hunting and food gathering. Matrilineal descent is not often found where food is grown by plowing; it is found primarily among peoples who live by agriculture but who do not use the plow.

Although early theorists tended to confuse matrilineality with matripotestality, and to consider that both were somehow inextricably combined with other traits to form a unity called matriarchy, such

rules are observed to vary from society to society. These theories were often based on the idea that human society had a single, inevitable line of evolutionary development, a position that most modern theorists have abandoned. Further, each argument relied on the doctrine of survivals (telltale traces of former states of organization from which the past history of the group could be reconstructed). Naïve application of the doctrine, and a tendency to see survivals whenever convenient led to the decline of most of these theories. Recent efforts have been directed toward the specification of conditions under which rules of descent may change; no attempt is made to guess at earliest origins or to trace development in a single line to the present. *See* KINSHIP; KINSHIP TERMINOLOGY; MARRIAGE, PRIMITIVE; *see* also references under "Matrilineality" in the Index.

MATRIX. The term matrix in mathematics is due to James Joseph Sylvester (1850), who applied it to a rectangular array of numbers "out of which determinants can be formed." The modern concept of a matrix as a hypercomplex number is due to William Rowan Hamilton (1853) and Arthur Cayley (1858). Matrix theory has found application in many branches of mathematics, including algebraic and differential equations, astronomy, mechanics, electric circuit theory, quantum mechanics, relativity, nuclear physics and aerodynamics. David Hilbert (1904) introduced matrices of infinite order in connection with a theory of integral equations. The theory of infinite matrices has grown into an important branch of mathematics.

A system of linear equations such as

$$\begin{aligned} 2x + y - 2z &= -2 \\ x - 3y + 5z &= 10 \\ 3x - y + 4z &= 13 \end{aligned}$$

determines two matrices, namely

$$\begin{bmatrix} 2 & 1 & -2 \\ 1 & -3 & 5 \\ 3 & -1 & 4 \end{bmatrix} \quad \begin{bmatrix} 2 & 1 & -2 & -2 \\ 1 & -3 & 5 & 10 \\ 3 & -1 & 4 & 13 \end{bmatrix}$$

The first is called the coefficient matrix, the second the augmented matrix. The system of equations is, in fact, essentially determined by the latter.

The commonly accepted definition of matrix is that of Sylvester, namely a rectangular array of numbers. Most authorities, however, feel that the definition is incomplete until the operations to which a matrix is subject have been defined and, therefore, prefer to define a matrix as a number of a total matrix algebra. A modern point of view consists in first defining linear transformations, or endomorphisms of a vector space, and investigating their properties. Then, since a matrix is a representation of a linear transformation, its properties may be defined from those of the linear transformation.

A total matrix algebra of order n^2 is the set of all n by n arrays, or matrices,

$$A = \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{n1} & a_{n2} & \cdots & a_{nn} \end{bmatrix}$$

whose elements a_{rs} are numbers of a given field or ring R , subject to the operations to be defined. If B is another such matrix, the sum $A+B$ is obtained by adding corresponding elements. The product $A \times B$ is the matrix whose element in row r and column s is the inner product of the r th row of A by the s th column of B , namely

$$a_{r1}b_{1s} + a_{r2}b_{2s} + \cdots + a_{rn}b_{ns}$$

A number of the field or ring R is called a scalar. The scalar

product kA of the matrix A by the scalar k is obtained by multiplying every element of A by k . Addition of matrices is associative and commutative, and multiplication is associative and distributive, but is not usually commutative.

The matrix O , each of whose elements is 0, is the identity of addition, since $O + A = A + O$ for every matrix A . The matrix

$$I = \begin{bmatrix} 1 & 0 & \cdots & 0 \\ 0 & 1 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & 1 \end{bmatrix}$$

having 1's in the main diagonal and 0's elsewhere is the identity of multiplication, and is called the identity matrix. A matrix having 0's in every position outside the main diagonal is called a diagonal matrix.

Determinant theory (see DETERMINANT) is properly a branch of the theory of matrices. Every square matrix has associated with it a scalar, called its determinant, which serves as a norm or absolute value. Thus the determinant of the product of two matrices is equal to the product of the determinants of the factors. A matrix whose determinant is not equal to zero is said to be nonsingular, and possesses an inverse A^{-1} such that $A^{-1}A = AA^{-1} = I$. A singular matrix has no inverse, but for every singular matrix A there is a nonzero matrix B such that $AB = BA = O$.

If x is an indeterminate, the matrix $A - xI$ is called the characteristic matrix of A , and its determinant $d(A - xI) = f(x)$ is called the characteristic function. The Hamilton-Cayley theorem states that $f(A) = O$; i.e., that every matrix satisfies its characteristic equation. Hence every n by n matrix satisfies an equation $m(x) = 0$ with scalar coefficients of minimum degree $\mu \leq n$. If $\mu < n$, the matrix is called derogatory. A square matrix may be considered as an operator transforming one vector into another. (See VECTOR ANALYSIS.) Thus

$$\begin{bmatrix} 2 & 1 & -2 \\ 1 & -3 & 5 \\ 3 & -1 & 4 \end{bmatrix} \begin{bmatrix} 1 \\ 2 \\ 3 \end{bmatrix} = \begin{bmatrix} -2 \\ 10 \\ 13 \end{bmatrix}$$

or $A\xi = \eta$. Thus the solution of a system of linear equations is the process of finding the vector ξ when the vector η and the matrix A are given. If A is nonsingular, $\xi = A^{-1}\eta$.

The rows of a matrix may be considered as a set of vectors, and the columns constitute another set of vectors. The number of linearly independent row vectors is equal to the number of linearly independent column vectors, and this number is called the rank of the matrix. The rank is also equal to the order of a nonsingular minor matrix of maximum order. The rank is not changed when a matrix is multiplied on either side by a nonsingular matrix. A system of linear equations in n unknowns has no solution unless the rank of the augmented matrix is equal to the rank of the coefficient matrix. If these ranks are both equal to r , there are $n - r$ linearly independent solutions, and every solution is a linear combination of these.

Calculations with matrices are much simplified by the use of elementary transformations (Hermann Grassmann, 1862, and Leopold Kronecker, 1866). Elementary transformations on the rows of a matrix are of three types: (1) the interchange of two rows; (2) the multiplication of the elements of a row by a unit of R ; (3) the addition to the elements of a row of k times the corresponding elements of any other row, k being in R . An elementary matrix is obtained by applying an elementary transformation to the identity matrix I . Every elementary transformation on the rows of a matrix A can be accomplished by multiplying A on the left by the corresponding elementary matrix. Analogous results hold for columns and right multipliers. Every unimodular matrix (i.e., a matrix whose determinant is a unit of R) is a product of a finite number of elementary matrices.

If P and Q are unimodular, the matrices A and $B = PAQ$ are called equivalent. Let the elements of A be either integers or polynomials in x . The quotients $h_i = d_i/d_{i-1}$, where d_i is the greatest common divisor of the i -rowed minor determinants of A , are called the invariant factors of A , and are invariant under the relation of equivalence. Two matrices are equivalent if and

only if they have the same invariant factors.

A linear homogeneous transformation $x'_i = \sum a_{ij}x_j$ can be written $\xi' = A\xi$ where ξ is the column vector whose components are x_1, x_2, \dots, x_n . The matrix A is called the matrix of the transformation. If new variables are introduced by means of the substitution $\xi = P\eta$, $\xi' = P\eta'$, then $\eta' = P^{-1}AP\eta$, which is a transformation of matrix $P^{-1}AP$. Such a substitution corresponds to a change of frame of reference in projective geometry.

If P is unimodular, the matrices A and $B = P^{-1}AP$ are called similar. Two matrices A and B with element in a field are similar if and only if their characteristic matrices $A - xI$ and $B - xI$ have the same invariant factors.

A homogeneous polynomial such as

$$\sum a_{ij}x_ix_j \quad (i, j = 1, 2, \dots, n)$$

is called a quadratic form. Such forms arise as the elements of length in differential geometry and the theory of relativity. There is no loss of generality in assuming that $A = (a_{ij})$ is a symmetric matrix—that is, $A = A^T$ where A^T (the transpose of A) is obtained from A by changing rows to columns. The quadratic form may be written $\xi^T A \xi$ where ξ^T is the row vector (x_1, x_2, \dots, x_n) and ξ is the column vector composed of the same letters. If new variables are introduced by means of the linear substitution $\xi = P\eta$, the new quadratic form $\eta^T P^T A P \eta$ has the (symmetric) matrix $P^T A P$.

Two symmetric matrices A and B are called congruent if a nonsingular matrix P exists such that $B = P^T A P$. If R is the real field, a matrix P can be found so that B has 0's everywhere except in the main diagonal, and with diagonal elements which are either 0 or 1 or -1 . The number of nonzero elements in the diagonal is the rank, and the number of 1's diminished by the number of -1 's is called the signature. These are invariants, and determine the matrix up to a congruence transformation.

In Euclidean geometry, an orthogonal transformation has a matrix P such that $P^T = P^{-1}$. Rotations are transformations of this type. An important problem is to reduce a quadratic form to diagonal form by means of an orthogonal transformation. Since $B = P^T A P = P^{-1} A P$, this is both a similarity transformation and a congruent transformation. If R is the real field, it is possible to find an orthogonal matrix P such that B is diagonal, its diagonal elements being the (real) roots of the characteristic equation of A .

MATSUDAIRA TSUNEO (1877–1949), Japanese diplomat and statesman, was born in Tokyo on April 17, 1877. In 1902, upon graduating from Tokyo Imperial university, he entered the diplomatic service. After assignments in China, England and France, he represented Japan in post-World War I discussions with the Soviet Union and also attended the Washington conference (1921–22). He then served as ambassador to Washington (1924–28), when U.S.-Japanese relations were strained by the Oriental Exclusion act passed by the United States congress. He was also ambassador to Great Britain (1929–36).

At the London Naval conference in 1930 Matsudaira helped secure an increase in Japan's allotted naval strength, which, however, failed to satisfy the rabid militarists at home. From 1936 to June 1945, as imperial household minister, he was a moderate adviser of the emperor.

In 1947, being elected to the diet, he became president of the

house of councilors (upper house). He died in Tokyo on Nov. 12, 1949. (Hn. Kn.)

MATSUE, ancient castle town of Japan on southwestern Honshu Island and capital of Shimane prefecture at 35° 28' N., 133° 04' E., is on a spit which cuts an arm of the Sea of Japan nearly in two. The city is a centre of land and sea communications and an important commercial centre. Political amalgamation with small adjacent villages from 1940 increased the area of the city from 3.8 sq.mi. to 67.1 sq.mi.; its population increased from 55,500 to 106,476 by the 1960 census. (C. A. Mr.)

MATSUKATA MASAYOSHI, PRINCE (1835-1924), Japanese statesman, was born in Kagoshima of a Satsuma samurai family on Aug. 17, 1835. As a young man he was a close friend of Okubo Toshimichi (q.v.), and it was in large part through the influence of Okubo that Matsukata became active in the movement to overthrow the shogunate.

In the new government Matsukata held the positions of governor of Tosa province (from 1868), assistant minister of finance (from 1874), home office (1880), and minister of finance (1881). But it was not until after Okubo's death in 1878 that Matsukata came into his own. After serving as the nation's representative at the Paris exposition of 1878, he returned to Japan to become the major advocate and executor of financial reform. The government had met the financial strain of modernization, which required great outlays, and of the suppression of the Satsuma rebellion (1877-78), by printing paper money. By the 1880s, currency was badly depreciated, specie was being hoarded, and government revenues, because of the fixed tax on land, were declining in value. Matsukata won the government over to a policy of stringent retrenchment. Government expenses were cut, factories owned by the government were sold to private buyers and paper money was redeemed. The Bank of Japan was founded with the right to issue convertible notes. In a period of three years the currency had been stabilized and government finances restored to health. Matsukata, who was created a prince in 1922, died at Tokyo on July 2, 1924. (T. C. Sh.)

MATSUMOTO, an industrial city in a mountain basin of central Japan, on Honshu Island, at 36° 14' N., 137° 58' E., is noted for its important silk industry. Silk production dates from feudal times when it was encouraged by the feudal lord or *daimyo*, because the price silk commanded would compensate for the cost of transportation over the mountain passes. Mulberry and fruit are grown on terraces encircling the floor of the basin. Hot springs and skiing resorts in the surrounding mountains made the city a tourist centre. The city increased in area from 7.3 sq.mi. in 1940 to 87.3 sq.mi.; the population increased from 72,800 to 148,710 between 1940 and the 1960 census. (C. A. Mr.)

MATSUO BASHŌ (pseudonym of MATSUO MUNEFUSA) (1644-1694), the greatest of the Japanese *haiku* poets, came from a minor samurai family of Ueno, Iga province, and was in the service of Sengin (the pen name of Yoshitada Tōdō), the son of the local lord, when he became interested in *haiku* (see JAPANESE LITERATURE). In 1666, after Sengin's death, Bashō gave up his life as a samurai to devote himself to this form of verse. In 1673 he moved to Edo (modern Tokyo), where he gradually acquired a reputation as a poet and critic. He attracted wide attention with the verse:

On a withered branch
A crow has alighted:
Nightfall in autumn.

In 1684 Bashō made the first of the journeys that figure so importantly in his work. His accounts of his travels are prized not only for the *haiku* that record various sights along the way but also for the equally beautiful prose passages that furnish the backgrounds. *Oku no Hosomichi* ("The Narrow Road of Oku," 1694), describing his visit in 1688 to northern Japan, is one of the loveliest works of Japanese literature.

The *haiku* previous to Bashō's emergence as a master had been subject to two evils: staleness, the result of the imposition of strangulating codes of rules intended to make this popular form of verse "respectable"; and ephemerality, the result of cramming with allusions to current gossip, supposedly so as to keep it lively

and up-to-date. Bashō, deploring both, insisted that the *haiku* must be at once unhackneyed and eternal; he advised his pupils, "Do not seek to follow in the footsteps of the men of old; seek what they sought."

On his travels Bashō also met local poets and engaged with them in the composition of linked verse (*renga*), an art in which he so excelled that some critics believe his linked verse was his finest work. When Bashō began writing in this medium the connection (or link) between successive verses had generally involved a pun or play on words, but he insisted that poets must go beyond mere verbal dexterity and link their verses by "perfume," "echo," "harmony" and other delicately conceived criteria.

One term frequently used to describe Bashō's poetry is *sabi*, which means the love of the old, the faded and the unobtrusive, a quality found in the verse:

Scent of chrysanthemums . . .
And in Nara
All the ancient Buddhas.

Here the musty smell of the chrysanthemums blends with the visual image of the dusty, flaking statues in the old capital. In still other verses a combination of the momentary and eternal suggests the Zen philosophy that underlies much of Bashō's work.

Bashō led a life of austerity that contrasted with the general flamboyance of his time. On occasion he withdrew from society altogether. Later men, honouring both the man and his poetry, revered him as the "saint of the *haiku*," and, indeed, no writer in Japan has been more loved or respected.

See Kenkichi Yamamoto, *Bashō* (1957); "The Narrow Road of Oku and Other Writings," Eng. trans. by Donald Keene (ed.) in *Anthology of Japanese Literature* (1955). (Dn. K.)

MATSUYAMA, seaport on the northwest coast of Shikoku Island, Japan, a tourist, industrial and communication centre and capital of Ehime prefecture, is located at 33° 50' N., 132° 46' E., in the rich agricultural Dogo plain. Since 1940 the city area has increased from 6.9 sq.mi. to 78.9 sq.mi.; the population rose from 117,500 to 238,604 between 1940 and the census of 1960. Cotton and synthetic textiles are the leading industries; lesser industries are chemicals, paper and machinery. The surrounding area produces citrus fruit, persimmons and loquats. Originally a castle town, Matsuyama still possesses an important castle museum and park. After World War II, the city was one of the first to use modern city planning in rebuilding. (C. A. Mr.)

MATTANCHERRI, a town in Ernakulam district of Kerala, India, and the commercial centre of the former Cochin state, lies on a backwater opposite to and 2 mi. S. of the port of Cochin (q.v.). Pop. (1961) 83,896. It is still a centre of import and export trade in which the Kutchi memons and banyas of Bombay have a large share. It has a spacious old palace of quaint Portuguese design (1555), where the rajas of Cochin resided. The palace contains mural paintings of exquisite design and rare execution. To the south lies the Jewish quarter, perhaps the only place in India that has synagogues. (G. Kn.)

MATTEOTTI, GIACOMO (1885-1924), Italian Socialist leader murdered for his opposition to the Fascist regime, was born at Fratta Polesine (Rovigo) on May 22, 1885. After graduating at Bologna he became a barrister and joined the Italian Socialist party. He was elected to the chamber of deputies in Nov. 1919, re-elected in May 1921 and finally re-elected again in April 1924, just after he had become secretary-general of his party. On May 30 he resolutely impugned the Fascist party before parliament. (The speech was published in London in 1924 as *The Fascisti Exposed*.)

On June 10, 1924, six *squadristi*, Amerigo Dumini, Augusto Malacria, Filippo Panzeri, Amleto Poveromo, Giuseppe Viola and Albino Volpi (allegedly hired by four leading Fascists, Cesare Rossi, Francesco Giunta, Giovanni Marinelli and Filippo Filippelli), seized Matteotti in Rome, took him by car to the thicket of Quartarella, near Riano Flaminio, murdered him and placed his body in a hastily dug hole. His disappearance was already causing a great sensation when, on Aug. 16, his body was accidentally discovered. The murder shook the regime and Mussolini ordered a judicial inquiry that lasted one and one-half years. On

March 24, 1926, at Chieti, the court of assizes found Dumini, Poveromo and Volpi guilty of "unintentional homicide" and sentenced them to 5 years, 11 months and 20 days of penal servitude. The other three were found not guilty. Two months later the Rome court of appeal remitted the three sentences.

After World War II the Italian government ordered a retrial, but by that time some of the accused men were either dead or fugitive. In 1947, in Rome, a special court of assizes sentenced Dumini, Poveromo and Viola to 30 years of penal servitude. Rossi and Giunta were acquitted for lack of evidence.

See M. del Giudice, *Cronistoria del processo Matteotti* (1954).

MATTER; see KINETIC THEORY OF MATTER; ATOM; NUCLEUS.

MATTERHORN (French MONT CERVIN; Ital. MONTE CERVINO), one of the best-known mountains (14,688 ft.) in the Alps, is on the frontier between Switzerland and Italy southwest of the village of Zermatt. Though on the Swiss side it appears to be an isolated horn-shaped peak, it is really the butt end of a ridge, and the Swiss slope is not nearly so steep or difficult as the grand terraced walls of the Italian slope. The Matterhorn was first conquered from the Swiss arête, after a number of attempts chiefly on the Italian side, on July 14, 1865, by Edward Whymper (q.v.), but four of his party fell to their death on the descent. Three days later it was scaled from the Italian side by a party of men from Val Tournanche led by J. A. Carrel. It is now frequently ascended in summer, especially from Zermatt.

MATTHAY, TOBIAS (1858–1945), English pianist, teacher and composer, was born in London on Feb. 19, 1858. He studied at the Royal Academy of Music and afterward taught there from 1876 to 1925, when he left to devote his attention to a piano school he had founded in 1900. In 1903 he published *The Art of Touch*, the first and most important of a number of books in which he made a detailed examination of the problems of piano technique, the interpretation of music and the psychology of teaching. Later publications included *The First Principles of Piano-forte Playing* (1905), *Relaxation Studies* (1908), *Musical Interpretation* (1913) and *On Method in Teaching* (1921). These books, together with his own teaching, brought him international fame and many pupils of distinction, the foremost of whom was Myra Hess. Matthay also composed music for the piano. He died at High Marley, near Haslemere, Surrey, on Dec. 15, 1945.

See Jessie Henderson Matthay, *The Life and Works of Tobias Matthay* (1945).

MATTHES, FRANÇOIS EMILE (1874–1948), U.S. geologist and topographer of some of the most rugged and scenic features of western United States, was born in Amsterdam, Neth., on March 16, 1874. His education, begun in Holland, Switzerland and Germany, was continued at Massachusetts Institute of Technology and Harvard university. He became a U.S. citizen in 1896 and as topographer with the U.S. geological survey (1896–1913) he mapped the Bighorn mountains, Glacier and Grand Canyon National parks, Yosemite valley, Mount Rainier and other western areas. His beautiful sketching on these maps has probably never been equaled. Later (1913–48) Matthes concentrated on geologic problems, attaining distinction as geomorphologist and glacialist. Investigations widely carried on in the Sierra Nevada, California, culminated in his classic *Geologic History of the Yosemite Valley* (1930). He organized the program of systematic glacier observations in North America, part of a world-wide study of climatic fluctuations as indicated by changes in existing glaciers. Matthes was an unusual linguist, highly artistic, and a writer of rare excellence. He died in Berkeley, Calif., on June 21, 1948.

(F. M. FL.)

MATTHESON, JOHANN (1681–1764), German composer and writer on musical theory and practice, was born Sept. 28, 1681, at Hamburg. From 1690 to 1705 he was a singer at the Hamburg opera and from 1699 he also worked there as composer and conductor. In 1704 he was appointed tutor to Cyrill, son of Sir John Wich, the English resident in Hamburg, and in 1706 he became secretary to Sir John and later to his successors. He held this position until 1755. While performing his secretarial work he also was organist at the Hamburg cathedral from 1715 to 1728. His musical activities were hampered by ear trouble that

started in 1705 and later led to total deafness. In 1709 he married an English woman, Catharine Jennings. He died in Hamburg on April 17, 1764.

Mattheson's compositions—operas, church music, serenades and chamber music—are of average quality, but as a writer on music his influence was great. He advocated the merging of Italian French and German styles in music; revitalizing church music, the use of equal temperament; the inclusion of women in church choirs; good musical education for musicians and adequate payment for their services. He fought against the use of solmization and against corruption and simony in musical life. His books are an inexhaustible source of information on German music of the 18th century.

Mattheson's numerous theoretical works include *Der vollkommene Capellmeister* (1739), an encyclopaedia of his musical ideas; *Grosse General-Bass-Schule* (1731) and *Kleine General-Bass-Schule* (1735) on the figured bass. He also wrote *Grundlage einer Ehrenpforte* (1740), which contains biographies of 148 composers and includes details of his own life. He translated English pamphlets, periodicals and books into German; e.g., Defoe's *Moll Flanders* (1723) and J. Mainwaring's *Memoirs of the Life of . . . Handel* (1761) with additional notes.

See B. C. Cannon, *Johann Mattheson* (1947).

(W. G. Bz.)

MATTHEW, SAINT, one of the Apostles of Christ. In Mark's list of the Twelve appointed by Christ (iii, 13–19), the name of Matthew is seventh, and is followed by that of Thomas. Apparently the evangelist made some attempt to arrange the names in the order of their eminence in the early church. His list may possibly indicate also that Matthew and Thomas were accustomed to work together; it was usual for Christian missionaries to work in pairs, and Mark records that Christ sent out the Twelve on a mission "two by two" (vi, 7). In the corresponding list in the third Gospel (Luke vi, 13–16) Matthew's name occurs in the same position. The first evangelist, who groups the names in pairs, gives "Thomas and Matthew" as the fourth (Matt. x, 3). A slightly different grouping is given in Luke's list of members of the primitive community in Jerusalem (Acts i, 13), "Philip and Thomas, Bartholomew and Matthew."

The first evangelist, however, when he records from Saint Mark the story of the call of Levi the tax collector, substitutes the name "Matthew" for that of "Levi the son of Alphaeus" (Matt. ix, 9; Mark ii, 14); he also adds "the tax collector" to Matthew's name in his list of the Twelve. According to tradition indeed it was Matthew himself who was the author of the first Gospel, but the tradition is undoubtedly a mistaken one. (See MATTHEW, GOSPEL ACCORDING TO SAINT.)

On the assumption that the identification of Matthew with Levi is correct, "Matthew" (probably meaning "Jehovah's gift") would appear to be the Christian name of Levi, who had been employed as a tax collector in the service of Herod Antipas, and whose call to be one of the immediate followers of Jesus Christ came to him as he sat at the tax office by the Sea of Galilee. It should be noted that Mark's story of his call resembles that of the call of Peter and Andrew and the sons of Zebedee, and one would expect to find Levi somewhere in his list of the Twelve. As a tax collector Levi would share in the distrust and contempt which these officials had earned for themselves everywhere.

According to Luke (v, 29) Levi after his call made a great feast for Jesus in his house. But the evangelist is here rewriting Mark, whose statement that "he was sitting at meat in his house" does not necessarily bear the meaning put upon it by Luke; Mark may mean that Jesus was entertaining friends at his own table, inserting the incident here as another illustration of the attitude of Jesus toward "tax collectors and sinners."

It will be seen that the New Testament affords only scanty and uncertain information in regard to Saint Matthew. Outside the New Testament the only statement of any importance in regard to the Apostle is the passage from Papias preserved by Eusebius: "So then Matthew composed the Oracles in the Hebrew language, and each one interpreted them as he could."

Legend differs as to the scene of the Apostle's missionary labours, and as to whether he died a natural or a martyr's death.

His feast day in the east is Nov. 16, in the west Sept. 21. See also APOSTLE.

(B. T. D. S.; X.)

MATTHEW, WILLIAM DILLER (1871-1947), North American vertebrate paleontologist known for his studies of fossil mammals, was born in Canada, at Saint John, New Brunswick, Feb. 19, 1871. After completing his studies at the University of New Brunswick and at Columbia University, New York City, he was associated with the American Museum of Natural History for 32 years. In 1927 he became professor of paleontology at the University of California. Matthew's initial work brought him in contact with thousands of specimens of fossil mammals in the collections of E. D. Cope. These and the work of Cope directed his life toward extensive studies of fossil mammals. Throughout his scientific research runs a progressive conservatism: Matthew valued facts above theories and materials above speculations.

His most widely known work is *Climate and Evolution* (1915), in which he gave strong support to the concept of holarctic radiation centres of mammals and preservation of primitive "relics" in the periphery of areas of radiation. Evolution and the importance of geological succession are ubiquitous themes in his studies. His other works include "Evolution of the Horse" (*Quart. Biol. Rev.*, 1915); "The Evolution of Mammals in the Eocene" (*Proc. Zool. Soc. Lond.*, 1927); "Faunas of the San Juan Basin" (*Mem. Amer. Philos. Soc.*, 1937, posthumous, ed. by Granger, Gregory, Colbert).

(E. C. O.)

MATTHEW, GOSPEL ACCORDING TO SAINT, in canonical order the first of the four Gospels, and thus the first book of the New Testament. Though the preferred "Gospel of the Church" since the 2nd century A.D., it was not chronologically the first Gospel. As one of the three Synoptic Gospels, Matthew used the Gospel of Mark as the primary source for most of its narrative material, while most of the sayings of Jesus in Matthew were drawn from Q, the Synoptic saying-source, which was also used by Luke (see GOSPELS).

Composition.—The framework of Matthew is taken from Mark with little modification, but Matthew frequently tries to establish a closer connection between isolated units, especially by filling in gaps in the Marcan composition (cf. Matt. iv, 12 with Mark i, 14, for example). Matthew often introduces chronological sequence or connects stories by a participial construction (e.g., "Jesus seeing/hearing this . . .", v, 1, etc.). The artificiality of such secondary combinations is most obvious in xiv, 13 where Matthew has forgotten that the death of John the Baptist was told in "parentheses" (xiv, 1-12) as having already occurred some time ago. Also, the dating of the material within the limits of certain days is quite unlikely if we begin to take this dating seriously: a single day would cover the material from v, 1 (Sermon on the Mount) through viii, 17 (including three healings), and the next day would include two crossings of the lake, five healing narratives and several discussions (viii, 18-ix, 34).

Although he usually takes his scenery and geography from Mark, the author of Matthew also independently adds the lake (ix, 1) the synagogue (ix, 35) and the mountain (v, 1; xv, 29); furthermore, he gives Jesus' activity a wider locale. It is no longer a private house (as in Mark) where Jesus teaches and instructs the disciples (xv, 15; xvii, 19; xix, 9), because Matthew is not interested in the theory of the Messiah secret (see MARK GOSPEL ACCORDING TO SAINT), but rather in stressing the public appeal of Jesus' ministry. "Great multitudes" are mentioned even more often than in Mark. The presence of the disciples is noticed more frequently, and their number, 12, is now taken for granted. Among the opponents, the Pharisees are particularly prominent and their hostility is emphasized more than in Mark (e.g., Matt. xxii, 34-41 compared with Mark xii, 28, 35; Matt. xv, 12; see also xxiii, 1-11).

Although Matthew did not basically change Mark's outline of Jesus' life, even a superficial examination of the former leaves the reader with an impression quite different from that derived from Mark. This is primarily because of the following factors: (1) Matthew adds further legendary materials, especially the birth narratives, and some new sections in the Passion account; (2) the author weaves the sayings taken from his second source (Q) into the Marcan framework; and (3) he arranges related mate-

rials in larger homogeneous sections—e.g., the Sermon on the Mount (v-vii) and the collection of miracle stories in viii-ix.

Outline.—The outline of Matthew must therefore follow the themes of the collected material rather than the geographical sequence, which remains basically the same as in Mark. (Matt. iii-xvi, 12, in and around Galilee; xvi, 13-xx, toward Jerusalem; xxi-xxvii, last days in Jerusalem and Passion.)

| xx, 17-28: | the church facing the Passion (third prediction, sons of Zebedee) |
| xx, 29-xxv, 46: | the Messiah of the "Last Days" |
| xx, 29-xxi, 17: | Jesus comes to Jerusalem (the two blind men of Jericho, entry into Jerusalem, cleansing of the Temple) |
| xxi, 18-xxii, 14: | Israel in its eschatological decision (curse of the fig tree and question about authority, parables of the two sons, the wicked husbandman and the marriage feast) |
| xxii, 15-xxiii, 36: | Jesus overcoming the Pharisees in controversy (tribute to Caesar, resurrection, great commandment, David's son, woes against the Pharisees) |
| xxiii, 37-xxv, 46: | the great eschatological discourse (the future of Jerusalem, "Synoptic Apocalypse," watchfulness of the disciples, the great eschatological parables) |
| xxvi, 1-xxviii, 20: | the Victory of the Messiah |
| xxvi, 1-46: | preparation for the Passion (anointing, betrayal, Last Supper, Gethsemane) |
| xxvi, 47-xxvii, 31: | trial of Jesus (and death of Judas) |
| xxvii, 32-46: | crucifixion and death, burial and guard at the tomb |
| xxviii, 1-20: | the Resurrection (the empty tomb, bribing of the soldiers, appearance in Galilee and command to baptize) |

Themes.—In Matthew, the adopted Marcan outline of the Gospel has been united with a thematic classification of the material. Sayings, collected into large discourses, have become the backbone of Matthew's composition. This indicates a fundamental

change in the way in which Jesus is viewed in the Gospel. According to Matthew the content of the Gospel is not Jesus' life and person, but the message and teachings in which Jesus interprets the Law and proclaims the New Righteousness. These teachings are presented by Matthew in the form of ecclesiastical instructions, with Jesus himself as teacher. It is legitimate, therefore, to call Matthew's Gospel a "manual of discipline" for the church, similar in many respects to the "manual of discipline" of the Essene community of Qumran, which also had its "Righteous Teacher" (see DEAD SEA SCROLLS). But the fundamental difference from the Essene community must not be overlooked; no messianic attribute is given to the Qumranic Righteous Teacher, whereas in Matthew the authoritative interpretation of the Law is precisely the ministry of Jesus as the Messiah. Consequently, there are two main aspects in the Gospel: (1) to feature Jesus as the divine Messiah, the eschatological Lord and Judge, and (2) to unfold Jesus' interpretation of the Law and His teachings as the guide and rule of the eschatological community as it confronts the coming Kingdom of God.

Matthew emphasizes Jesus' divinity in several ways. It is already explicit in the birth narratives. Significantly, the messianic fulfillment of Old Testament prophecy is underlined throughout the Gospel by the "formula quotations": "This happened in order to fulfill what was said . . ." (i, 22; ii, 15, 17, 23, etc.). The miracle stories are significantly altered by Matthew to show Jesus not as the powerful Messiah but rather as the merciful King (compare, e.g., Matt. ix, 18-26 with Mark v, 21-43) who fulfills the words of the prophets by saving His people from sickness (see viii, 16-17, ix, 35-36; xi, 2-6). The Christological titles given to Jesus are presented as testimonies that Old Testament expectations are accomplished in his person (Messiah, Son of David, Lord, King of Israel, Son of Man, Son of God). They go far beyond the titles given to a "teacher," and Jesus' disciples (except Judas; see xxvi, 25) never use this form of address, but always the title of divine majesty, "Lord" (compare Matt. viii, 25 with Mark iv, 38). Matthew, more consistently than Mark, identifies Jesus with the future Messiah and Judge (compare Matt. x, 33 with Mark ix, 37).

According to Matthew, the centre of Jesus' messianic ministry of fulfillment is His teaching. To fulfill and to re-establish the Law is the chief task of the Messiah. It is not a new law that Jesus proclaims, but the old and only Law of God as it was given through Moses and the Prophets, and which is reinforced in its entire validity including every "iota and dot" (v, 18-19). What is "new" is the righteousness Jesus requires—an obedience that recognizes God's radical demand upon man's existence as it is made clear in Jesus' interpretation of the Law (v, 21-48). This New Righteousness, which must "exceed that of the Scribes and Pharisees," is the condition for the entrance into the Kingdom (v, 20). The five great discourses in Matthew unfold this "Law" as the demand for a New Righteousness in its full eschatological dimension.

All these discourses (v-vii; x; xiii; xviii; xxiii-xxv) follow the same pattern of eschatological church instruction: (1) the announcement of the essentials of the re-established law; (2) detailed regulations for the life of each individual and the church as a whole; and (3) an eschatological appeal and warning. This pattern goes back to the Old Testament covenant formula, and in the early church is used especially in "catechisms" like the Teaching of the Twelve Apostles (see APOSTOLIC FATHERS). Even the sequence of Matthew's various discourses follows this general pattern.

The Matthean understanding of the nature of the church also is revealed through this arrangement of the materials. For the first time, Jesus is depicted as the founder of the church in Matt. xvi, 17-19 (here and in xviii, 17 are found the only use of the word "church" in the Gospels). This debated passage (which is often used as a proof-text for the Petrine-Roman "power of keys") stresses that the church as the eschatological community possesses the promise that the doors of hell shall not be able to overcome it in its eschatological trouble. Thus the concept of the church is rooted in the eschatological perspective. The stilling of the

tempest (Matt. viii, 23-27) becomes a paradigm for the church in the apocalyptic earthquakes. The relation between Jesus and His disciples prefigures the relation between the risen Lord and His church in the terrors and torments that will precede the Second Coming (xxiv, 3-8). The church is always pictured in a situation of persecution and exposed to dangers from within and without—a feature emphasized at the end of every discourse.

It is in this eschatological setting that uncompromising obedience, the New Righteousness, becomes relevant. To do good works (vii, 16-23), to love one's enemies (v, 43-47), to refrain from retaliation (v, 38-42), to forgive continually (xviii, 21-22)—in short, the commandment of love as the fulfillment of the Law (xxii, 36-40)—is the demand upon the true disciple who aspires to achieve the eschatological quality of "perfection" (v, 48; xix, 21). Every compromise excludes from the Kingdom, but "blessed are those who are persecuted for righteousness' sake" (v, 10; this beatitude is added by Matthew to the traditional beatitudes of Jesus). This, however, does not mean blind subordination or fatalistic endurance. Matthew often stresses the necessity of real insight and understanding (compare Matt. xiii, 19-23 with Mark iv, 15-20), and eschatological watchfulness is synonymous with ethical preparedness (xxii, 11-13, etc.). Christology, ecclesiology and eschatology thus are bound together by the concept of Law and New Righteousness. Christian life is mature responsibility in view of the final judgment of each man's works. Jesus as the Messiah is the teacher of the Law, the Lord of the obedient church and the Judge of the Last Day. Consequently the Gospel is not presented in Matthew as the eternal doctrine about some superhuman being, but as the message of that Jesus who Himself has suffered and died as the archetype of the true disciple.

Literary History.—With its strong emphasis upon the Law and its constant dispute with the leaders of Judaism, Matthew certainly was written for a Jewish-Christian church in a strongly Jewish environment. But, although the uniquely Matthean tradition presupposes the scholarly work of teachers acquainted with the Hebrew language, the Gospel itself belongs to Greek-speaking Christianity. Its main sources are Greek writings (Mark and Q), and the author often substitutes more fluent Greek idioms for the clumsy sentences of his sources. Thus, the Gospel must have been written somewhere outside Palestine in a strong Greek-speaking Jewish community. Since Matthew probably was used first by Ignatius of Antioch (A.D. 110), the coastal district of Syria is still the best suggestion of a possible place of origin, although the city of Antioch itself is unlikely because it also was influenced by Pauline teachings, which are lacking in Matthew.

All these evidences also belie the statement of Papias that the Gospel was written first in Hebrew by the disciple Matthew (see GOSPELS). Since the fall of Jerusalem in A.D. 70 is clearly presupposed in xxii, 6-7 (cf. xxiii, 37-39), and since the name of Levi the tax collector in Mark ii, 14 is changed to Matthew in Matt. ix, 9 it seems clear that the author was a later writer who claimed Matthew's authority for his Gospel, rather than the disciple himself. The dependence on written sources, school traditions and developed Christological, doctrinal and liturgical formulations point to a man of third-generation Christianity who composed the Gospel between A.D. 75 and 100. MATTHEW PARIS: see PARIS, MATTHEW.

MATTHEWS, (JAMES) BRANDER (1852–1929), U.S. essayist and dramatic critic, chief U.S. advocate of the "well-made" play of the Jones-Pinero school, was born in New Orleans, La., Feb. 21, 1852, and educated at Columbia university (A.B., 1871; LL.B., 1873; A.M., 1874). Though admitted to the bar he never practised but turned instead to writing and the study of literature. He was professor of literature at Columbia, 1892–1900, and of dramatic literature, 1900–24. A prominent figure in New York literary groups, Matthews was the author of many short stories and critical essays, was a regular critic for the *New York Times* for a long period, and published more than 40 books (as author or editor). His scholarship, revealed in such works as *Molière, His Life and His Works* (1910), *Shakespeare as a Playwright* (1913) and *French Dramatists of the 19th Century* (1881), is sound, although in his lighter essays there is much repetition. He died in New York city on March 31, 1929.

MATTHIAS, SAINT, the disciple chosen to fill the place vacated by Judas Iscariot (Acts i, 21–26). The primitive method of choice (by lot), the Aramaic form of the name (a shortened form of Mattathias and not Grecized like the better-known Matthew), and the fact that Paul received a tradition which referred to "the twelve" as distinguished from "all the apostles" (I Cor. xv, 5–7) lead to the inference that the story is based upon actual fact. The choice of twelve disciples by Jesus points to a consciousness of a nation-wide mission, which was contained in the community after the crucifixion. Matthias is not mentioned again in the New Testament. Clement of Alexandria refers to the "Traditions" of Matthias; some, he says, identified him with Zacchaeus the publican. *The Acts of Andrew and Matthias* is a romance preserved in Greek and Syriac and, in part, in Latin. In it Matthias goes to the anthropophagi, where he has remarkable adventures. St. Matthias' feast day is Feb. 24 (Feb. 25 in leap year) in the Western Church and Aug. 9 in the Greek Church.

(W. K. L. C.)

MATTHIAS (1557–1619), Holy Roman emperor from 1612, also king of Hungary from 1608 to 1618 and of Bohemia from 1611 to 1617, was born in Vienna on Feb. 24, 1557, the third son of the future emperor Maximilian II and Maria, daughter of the emperor Charles V. He was educated in Spain by the learned diplomat Augier Ghislain de Busbecq. His father, who died in 1576, left no territories to him. On the invitation of the Catholic nobility of the Netherlands, Matthias went to Brussels in Oct. 1577 to take the place of his uncle Philip II's governor general there, Don John of Austria, and to mediate in the quarrel between the Netherlands and Spain; in Jan. 1578 the states-general appointed him governor general. He found himself, however, unable to do anything without William of Orange, to counteract whose influence he had been invited; and in Oct. 1581 he finally left the Netherlands for Germany.

Matthias now sought to obtain a governorship in the Habsburg lands, but not until 1593 did his eldest brother, the emperor Rudolf II, appoint him governor of Austria. There he furthered the work of the Counter Reformation against the Protestants (although tolerating Protestants in his household), suppressed risings of the Protestant peasants between 1594 and 1597 and fought against the Turks. He was only partly successful in all these activities. From c. 1598 onward Matthias relied increasingly on the advice of the ecclesiastical statesman Melchior Klesl (q.v.).

Meanwhile, the discontent of members of the house of Habsburg at Rudolf's political inactivity grew until, in 1605, they forced him to empower Matthias to conduct affairs in Hungary, which had revolted under István Bocskay. In April 1606 the Habsburg archdukes, temporarily united, recognized Matthias (whose second elder brother Ernest had died in 1595) as their head and as Rudolf's successor. Matthias made peace with the Hungarians at Vienna on June 23, 1606, granting to the estates religious freedom both for Lutherans and for Calvinists and some political independence. The armistice that he concluded with the sultan Ahmed I at Zsitvatorök (Nov. 11, 1606) was broken in 1611 but was reaffirmed in 1615, inaugurating a period of peace between the Habsburgs and the Turks that lasted till 1663.

Rudolf, henceforward full of suspicion toward Matthias, disliked the peace policy and prepared to renew the Turkish war but Matthias, in alliance with the estates of Hungary, Austria and Moravia, forced Rudolf to cede these lands to him in June 1608 and to promise him the succession in Bohemia as well as in Rudolf's other lands. Matthias, who was crowned king of Hungary in Nov. 1608, was compelled by the estates of Hungary, Austria and Moravia to grant them further religious concessions. The formal reconciliation of 1610 between Matthias and Rudolf was broken in 1611, when the Bohemian estates asked Matthias for assistance against Rudolf's mutinous troops, which were ravaging Bohemia under the archduke Leopold (1586–1632) with Rudolf's connivance. The estates forced Rudolf to abdicate, and Matthias was crowned king of Bohemia on May 23, 1611. Rudolf prevented Matthias' preliminary election as king of the Romans, or successor designate to the empire, but died on Jan. 20, 1612. Then Matthias was elected on June 13 and crowned emperor on June 24, 1612. He also succeeded to Rudolf's remaining lands.

In Dec. 1611 Matthias had married his cousin Anna of Tirol (1585–1618), daughter of his uncle the archduke Ferdinand (1529–95). Devoting himself to his household and to patronage of the arts, Matthias neglected public affairs, the conduct of which was mostly left to Klesl. Matthias and Klesl failed in their attempts to reconcile the contending religious parties of Germany and to revive the imperial institutions, which had ceased to function. Imperial instructions were ignored in the continuing dispute over the succession to Jülich and Cleves. Matthias' only success was to prevent a confederation of the estates of all the Habsburg lands in 1615. The unyielding Catholic princes of Germany received support in their opposition to Klesl's peaceful policy from the younger Habsburgs, led by the emperor's brother, the archduke Maximilian (1558–1618), and by his cousin, the archduke Ferdinand of Styria, afterward the emperor Ferdinand II. The archdukes decided that Ferdinand should succeed Matthias, who was old, ill and childless, as emperor. Ferdinand was accepted as king of Bohemia in 1617 and crowned king of Hungary in 1618, but met with Protestant resistance in Bohemia. Matthias and Klesl advised concessions to the rebels, but Ferdinand and Maximilian defeated this policy by imprisoning Klesl. Matthias died at Vienna on March 20, 1619, just when the Bohemian struggles were leading into the Thirty Years' War.

MATTHIAS I CORVINUS (MÁTYÁS HUNYADI) (1440–1490), king of Hungary from 1458 and of Bohemia from 1469 to 1478, was born probably on Feb. 23, 1440, at Kolozsvár (Cluj) in Transylvania, the second son of János Hunyadi (q.v.) and Elizabeth Szilágyi. He shared in his father's campaigns when only 12 years of age. He was created count of Beszterce (Bistrita) in 1453 and knighted at the siege of Belgrade in 1454. At 15 he was married to Elizabeth of Cilli (Celje), but the young Elizabeth died before the marriage was consummated. On his father's death (1456) he was inveigled to Buda by his enemies and condemned to death on the pretext of an imaginary conspiracy, but was spared on account of his youth. On King László V's death (1457), he was detained for a time by George of Podebrady, governor of Bohemia, who treated him hospitably and affianced him to his daughter Catherine. On Jan. 24, 1458, Matthias was elected king of Hungary by acclamation, though a section of the magnates, headed by the palatine László Garai and by the governor of Transylvania, Miklós Ujlaki, was opposed to him; and on Feb. 14 he entered Buda in state.

The situation of Hungary was precarious, and to the king's numerous foreign enemies were added the magnates, headed by his own uncle and guardian, Mihály Szilágyi. Despite their opposition, Matthias, on Feb. 9, 1458, married Catherine of Podebrady, whose father was crowned king of Bohemia soon afterward. Matthias was now able to fight against the Turks, to invade Serbia and to reassert his suzerainty over Bosnia. After malcontents had actually crowned the Holy Roman emperor

Frederick III as king of Hungary at Wiener Neustadt (March 4, 1459), Matthias drove him out. In April 1462 the emperor was forced to recognize Matthias as king of Hungary and to give up the crown of that country. He was allowed, however, to retain certain Hungarian counties with the title of king. After a campaign against the Turks, during which he invaded Bosnia successfully, Matthias was crowned king of Hungary on March 29, 1464. Having joined the Catholic league against his father-in-law, George of Podebrady, in 1468, he was elected king of Bohemia by the Czech Catholics on May 3, 1469. George of Podebrady, however, allied himself with the Poles; and after years of fighting and maneuvering against the counterclaimant Wladyslaw (son of Casimir IV of Poland) and against the emperor Frederick, Matthias was forced at last, under the peace of Olomouc in 1478, to recognize the Pole as king of Bohemia (Vladislav II), while he himself secured Moravia, Silesia and Lusatia until they should be redeemed for 400,000 florins.

The emperor promised to pay Matthias 100,000 florins as war indemnity and recognized him as the legitimate king of Hungary on the understanding that he (the emperor) should succeed him in the then unlikely event of his dying without legitimate issue (a widower since 1464, Matthias had married his third wife, Beatrice of Aragon, daughter of Ferdinand I of Naples, on Dec. 15, 1476). In his third war against Frederick, which began in 1481, Matthias was rapidly successful. He entered Vienna (which he made his capital thenceforward) on June 1, 1485, and proceeded to conquer Styria, Carinthia and Carniola. He consolidated his position by alliances with the dukes of Saxony and of Bavaria, with the Swiss confederation and with the archbishop of Salzburg and furthermore extended his influence southward into Italy. Henceforth he was the greatest potentate in central Europe.

Though his policy was so predominantly directed toward the west that he soon abandoned his youthful idea of driving the Turks out of Europe, Matthias at least succeeded in making them respect Hungarian territory and in pushing his frontier southward in Bosnia. He had no children by Beatrice, and his last days were occupied in trying to secure the succession for János (John) Corvinus, his illegitimate son by a Breslau burgher's daughter. Beatrice, however, opposed this project fiercely, and the matter was still unsettled when Matthias died suddenly in Vienna on April 6, 1490.

Matthias Hunyadi was the greatest prince of his day. He was illustrious as a soldier, a statesman, an orator, a legislator and an administrator. Although naturally passionate and repeatedly provoked, he was never cruel or vindictive. It was said that often half his nights were spent in reading, after the labour of his most strenuous days. His camp was a school of chivalry, and humanist culture had its heyday in Hungary during his reign. His library, the Corvina, was famous the world over, and he had a fine collection of illuminated codices. In his luxurious residences of Buda and Visegrád, he surrounded himself with humanists, poets and artists. He established the first printing press in Buda and founded the University of Pozsony (Bratislava) and a college in Buda.

See also references under "Matthias I Corvinus" in the Index. (GE. GR.)

MATTHISSON, FRIEDRICH VON (1761–1831), German poet whose verse was praised by Schiller for its melancholy sweetness and its fine description of scenery, was born near Magdeburg on Jan. 23, 1761. In 1812 he was appointed intendant of the court theatre and chief librarian of the royal library at Stuttgart. In 1828 he retired and settled at Wörlitz near Dessau, where he died on March 12, 1831. Matthiesson's poems, *Gedichte*, were published in 1787. His poem "Adelaide" remains famous in a setting by Beethoven.

BIBLIOGRAPHY.—Matthiesson's *Schriften* appeared in 8 vol. (1825–29): vol. 1 collects his poems; vol. 2–8 his reminiscences. A supplementary volume (1833) contains a biography by H. Döring. There is a 2-vol. ed. by G. Bolsing (1812–13). A selection from his correspondence, ed. by F. R. Schoch, appeared in 4 vol. (1832). See also W. Krebs, *Friedrich von Matthiesson* (1912); A. Heers, *Das Leben Friedrich von Matthiesson* (1913).

MATTING, a general term for woven or plaited mats of

vegetable fibres and similar articles of other materials, used as floor coverings, carpet cushioning or underpads, table mats, hangings, wrappings, etc. Materials used in vegetable fibre matting include straw, bulrushes, fibres and leaves of several palms and the screw pine, munj or munja grass and mat grasses. Various natural and man-made fibres, usually in a blend, are used in non-woven matting (see FELT). Floor mats for automobiles and other means of transportation are frequently made of rubber; some door mats are made of woven wire. The term matting also includes some types of foam rubber, used in industry.

A coarse floor covering ideal for summer use is made from coir (*q.v.*), a fibre of the coconut palm, and from other bast fibres such as cane, manila hemp, abaca, henequen and various grasses and rushes. The fibres are made into yarn which is then woven into a coarse fabric on heavy, wide looms. Simple weaves are used and patterns may be plain, striped, checked, twilled, etc. The fabric may be woven to size or cut to size; if it is cut, the pieces are bound around the edges by a rope or strand of the material but the selvage edges are usually left unbound.

Another type is made from strands or rope formations by arranging alternate layers in sinuous and straight paths and then stitching the parts together. This matting finds use as the outer covering for the fenders of ships. (G. E. L.)

MATVEEV, ARTAMON SERGEEVICH (1625–1682), Russian diplomat and statesman, the friend and the influential adviser of the tsar Alexis, was the son of an obscure government clerk. By 1654 Matveev had risen to the rank of chief of the Moscow *streltsy* (household troops) and in that year negotiated with the Poles the surrender of Smolensk to Russia. He replaced A. L. Ordyn-Nashchokin at the head of the department for Ukrainian affairs in 1669 and at the head of the foreign department in 1671. Unlike his predecessor, he favoured a policy leading to the incorporation of the whole Ukraine in Muscovy, but was hindered in its execution by the re-emergence of the Turkish threat to Europe. His policy toward the west foreshadowed that of V. V. Golitsyn. In 1672 he took a prominent part in the conclusion of an agreement with Poland about concerted action against Turkey. When, later in 1672, Kamenets fell to the Turks, Matveev dispatched envoys to Austria, Brandenburg, France, Spain, Venice, the Holy See, Sweden and Holland to enlist support against Turkey. A manual of diplomatic correspondence was compiled by the clerks of the foreign department during Matveev's term of office. His influence on the tsar Alexis, already great, increased with the tsar's marriage (1671) to Matveev's ward, Natalia Kirillovna Naryshkina; but only in 1674 was Matveev, whose low birth handicapped him, made a privy councillor. On the accession of the tsar Fedor Alekseevich in 1676, Matveev was accused of black magic and fraud, deprived of his rank and possessions and exiled. In Jan. 1682 he was pardoned and allowed to reside at Lukh, whence Peter I, on succeeding Fedor in April, was induced to recall him to Moscow. On May 25 (new style; 15, old style), 1682, four days after his return, he was killed by the rebellious *streltsy*.

Matveev's intellectual horizon was uncommonly wide for a Muscovite of his day. In 1672 he arranged the first theatrical performance to be given at the Russian court. His way of life bore witness to his westernizing inclinations: his wife appeared in male society and his house was furnished after the western fashion. (L. R. LR.)

MAU: see IRENG.

MAUBIN, a district in the Irrawaddy delta of the Union of Burma, lying to the west of Rangoon. Area 1,651 sq. mi. Pop. (1962 est.) 576,546. In the rainy season (June–September) when the rice fields are flooded, only the huts, strung out along the banks of the delta creeks, appear to rise above the floods; in the dry season the paddy fields are brown and dry but numerous freshwater marshes remain. Communication is by water; Maubin town is on the west bank of the main Irrawaddy distributary and is linked directly with Rangoon by the Twante canal. Opposite Maubin is a very large unreclaimed freshwater swamp. (L. D. S.)

MAUCH CHUNK: see JIM THORPE.

MAUCHLINE, a village and civil parish of Ayrshire, Scot., 9 mi. S.E. of Kilmarnock and 11 mi. E.N.E. of Ayr by road. Pop. (1961) 4,454. It is situated on a gentle slope about 1 mi. from the river Ayr. On the village green a monument marks the spot where five Covenanters were killed in 1685. Mauchline is the site of the Burns National memorial and has many links with the poet, who lived with his brother Gilbert on the farm of Mossiel, about a mile to the north, from 1784 to 1788. In Castle street is the house (now a museum) where Robert Burns and Jean Armour stayed before going to Ellisland. Mauchline kirkyard was the scene of the "Holy Fair"; the "Jolly Beggars" met at "Poosie Nansie's"—still, though much altered, a popular inn; "auld Nanse Tinnock's" house nearly faces the entrance to the churchyard; the Rev. William Auld was minister of Mauchline, and "Holy Willie," whom the poet scoured in the celebrated "Prayer," was one of "Daddy Auld's" elders. Behind the kirkyard stands the house of Gavin Hamilton, the lawyer and firm friend of Burns, in which the poet was married. The braes of Ballochmyle, where he met the heroine of his song, "The Lass o' Ballochmyle," lie about a mile to the southeast.

Its industries are coal mining and the making of curling stones, optical instruments, powdered milk and agricultural implements.

MAUGHAM, WILLIAM SOMERSET (1874–1965), English novelist, playwright and short-story writer, whose work is characterized by a clear unadorned style, cosmopolitan settings and a shrewd understanding of human nature, was born in Paris on Jan. 25, 1874. Orphaned at the age of ten, he was brought up by an uncle and educated at King's school, Canterbury. After a year at Heidelberg, he entered St. Thomas's medical school and qualified as a doctor in 1897. He drew on his experiences as an obstetrician in his first novel, *Liza of Lambeth* (1897), and its success, though small, encouraged him to abandon medicine. He traveled in Spain and Italy and in 1908 achieved a theatrical triumph, with four plays running at once, which brought him financial security. During World War I he worked as a secret agent. After the war he traveled widely, and in 1928 bought a villa on Cape Ferrat in the south of France which became his permanent home, and where he died on Dec. 16, 1965.

His reputation as a novelist rests primarily on four books: *Of Human Bondage* (1915), a semiautobiographical account of a young medical student's painful progress toward maturity; *The Moon and Sixpence* (1919), an account of an unconventional artist suggested by the life of Paul Gauguin; *Cakes and Ale* (1930), the story of a famous novelist, which was thought to contain caricatures of Thomas Hardy and Hugh Walpole; and *The Razor's Edge* (1944), a young American war veteran's quest for a satisfying way of life. Maugham's plays, mainly Edwardian social comedies, soon dated, but his short stories (complete edition, 3 volumes, 1951) have steadily increased in popularity. They often portray the conflict of Europeans in alien surroundings which provoke strong emotions, and Maugham's skill in handling plot, in the manner of Guy de Maupassant, is distinguished by economy and suspense. In *The Summing Up* (1938) and *A Writer's Notebook* (1949) Maugham explains his philosophy of life: a resigned atheism and a certain skepticism about the extent of man's innate goodness and intelligence; it is this which gives his work its astringent cynicism.

See R. A. Cordell, *Somerset Maugham* (1961); William Somerset Maugham, *Selected Prefaces and Introductions* (1964).

MAUKHARI, a north Indian ruling family or clan, prominent in the 6th century A.D. The earliest reference to the Maukharis is on a seal of the Mauryan period, found at Gaya in south Bihar. They appear again in sacrificial inscriptions at Kotah in Rajasthan, dated A.D. 239. A further Maukhari family ruled in the 5th century in the Gaya district.

The most important branch of the Maukhari family, however, is not known to have been directly connected with those mentioned above, and seems to have had its main centre to the north of the Ganges. Originally feudatory chiefs of the Gupta empire, the Maukharis asserted their independence on its decline, and by 554 their king Isanavarman had thrown off all allegiance and had taken imperial titles. The second half of the century saw continuous

conflict between the Maukharis and the kings of the later Gupta line. The Maukharis seem to have ruled much of modern Uttar Pradesh, their power sometimes extending into parts of Magadha (south Bihar); there is also some evidence of Maukhari raids in the Deccan. Their capital was Kanyakubja (Kannauj), and they were mainly responsible for developing this city.

The last significant Maukhari king, Grahavarman, was defeated and killed by the Guptas soon after his accession, and his capital was occupied. His brother-in-law Harsha (q.v.), however, expelled the Guptas c. 606 and thus gained control of the Maukhari kingdom. After this the Maukhari family is hardly heard of again.

See E. Pires, *The Maukharis* (1934); R. S. Tripathi, *History of Kanauj* (1937). (A. L. BA.)

MAULE, a coastal range province of central Chile. It was created in 1826. In 1927 Linares province (q.v.) was annexed, the capital moved to Linares and Itata department transferred to Ñuble province (q.v.). In 1936 Maule and Linares provinces were separated and Maule's capital was re-established at Cauquenes (pop. [1960] 17,836). Area 2,200 sq.mi. Pop. (1960) 79,763. Maule is the least densely populated province between the Bío-Bío and Aconcagua valleys. Its rolling hill terrain is brush covered in the east but becomes forested in the centre and west. The accessible hardwood forests have been cut over and in some areas replaced by pine and eucalyptus plantations. Sheep and cattle range everywhere. Agriculture is concentrated in the valleys, chief among them the Cauquenes. Most valuable crop is the vine, but wheat, various legumes and maize are important. The products of field, range and forest may be shipped on the Cauquenes-Parral or Constitución-Talca branches of the state railway. The latter line parallels the Maule river, one of central Chile's larger streams. Small ships enter the lower river and barges carry logs, pulp and firewood to Constitución or across the river to the railroad.

Constitución (pop. [1960] 9,536) remains a minor port although considerable effort has been made to scour the river mouth and build an artificial harbour nearby. Wooden ships and barges are constructed, and a summer vacation trade is attracted by the picturesque town, wooded hills, cliff coast and beaches. Constitución, Chanco (pop. [1960 mun.] 11,759) and Cauquenes are departmental seats. The Maule river is said to have represented the southern limit of the Inca empire. (J. T.)

MAUNDY THURSDAY, the Thursday before Easter, is so called from the first word of an anthem sung on this day in Roman Catholic churches: *Mandatum novum do vobis* ("a new commandment I give to you"; John xiii, 34). From earliest times the day has been observed in commemoration of Christ's institution of the Eucharist with a general communion of clergy and people. At a special Mass the bishop consecrated the holy oils in preparation for the anointing of the neophytes at the baptism on Easter night. Since 1956 Maundy Thursday has been celebrated in Roman Catholic churches with a morning Mass for the consecration of the holy oils (in cathedrals) for the coming year and an evening Mass in commemoration of the institution of the Lord's Supper with general communion; during this Mass occurs the ceremony of the washing of feet (*pedilavium*, known more generally as the *Mandatum*) when the celebrant ceremonially washes the feet of 12 men in memory of Christ's washing the feet of his disciples. At this Mass the hosts are consecrated for the communion on Good Friday (when there is no Mass). Orthodox churches also have a ceremony of foot-washing and a blessing of oil on this day.

The Maundy ceremony, usually held at Westminster abbey, London, when alms are distributed on behalf of the British sovereign, is a relic of the former practice whereby sovereigns used to wash the feet of the poor on this day. In most European countries Maundy Thursday is known as "Holy Thursday"; other names are "Green Thursday" (common in Germany, *Gründonnerstag*), from the early practice of giving penitents a green branch in token that their Lenten penance was completed, and "Sheer Thursday" (that is, "clean Thursday"), a reference to the ceremonial washing of altars on this day. See also HOLY WEEK; LENT.

MAUPASSANT, (HENRY RENÉ ALBERT) GUY DE (1850-1893), French writer of short stories and novels whose work is distinguished from that of other naturalists both by its universality and by the purity of its style and who is remembered also for the tragic circumstances of his life, was born in the château of Miromesnil, near Dieppe (Seine-Inférieure), on Aug. 5, 1850. His father, Gustave de Maupassant, who had a partnership in a Paris firm of stockbrokers, had in 1846 married Laure Le Poittevin, sister of Gustave Flaubert's friend Alfred Le Poittevin, who himself in the same year had married Gustave de Maupassant's sister Louise. This double link explains why Flaubert took so affectionate an interest in his friend's nephew after Alfred's death in 1848. Because of disagreements with her husband Mme de Maupassant went to live on her estate Les Verguies, at Étretat, after the birth of her younger son Hervé (1856). There, in wild surroundings, Guy grew up in the company of sailors' and peasants' children. Having learned Latin from the vicar, he was sent at the age of 13 to a Catholic school at Yvetot, but was expelled after less than two years, without regret on his part, and passed to the Rouen *lycée*. His poem "Le Dieu créateur," which won a prize in the philosophy class there, shows the influence of Alfred de Vigny's pessimism, of Victor Hugo's pantheism and also of the conversations that he heard between Flaubert and Louis Bouilhet, with whom he spent his Sundays in termtime. In 1867 he matriculated at Caen university. For his holidays he used to go back to Étretat. There, in the summer of 1868, he met the English poet Swinburne and his friend George Powell. The house and the dinner to which these two invited the young Maupassant made a vivid impression on him, which was reflected in one of his first stories ("La Main d'écorché," published under the pseudonym Joseph Prunier in 1875) and reproduced in his preface to Gabriel Mourey's translation of Swinburne's *Poems and Ballads* (1891).

Enlistment in the army on the outbreak of the Franco-German War in 1870 interrupted Maupassant's work as a law student, and after his discharge (autumn 1871) he secured a post as a clerk in the ministry of marine in Feb. 1873. This gave him some insight into the office workers' way of life, which he was later to exploit in stories such as "Les Dimanches d'un bourgeois de Paris" (1882) and "L'Héritage" (1884). Meanwhile Maupassant divided his spare time between rowing on the Seine and writing. Everything that he wrote he submitted to Flaubert, who called him his disciple and proved himself an exacting critic, forbidding Maupassant to publish anything before he had formed his style and matured his personality. Flaubert moreover encouraged him to write verse, so as to make his prose style more supple. Thus it was that Maupassant's first book was a collection of poems, *Des Vers* (1880). One of these poems, which had first appeared under the title "Au bord de l'eau" in a periodical in 1876, had been threatened with prosecution on the grounds of indecency when it was reprinted as "Une fille" in another periodical in 1879, but the case was dropped thanks to Flaubert's intervention. Flaubert furthermore persuaded his friend Agénor Bardoux, who was then minister of education, to give Maupassant a secretarial appointment in his office instead of his post at the ministry of marine. He had also introduced him to other writers, Zola, Daudet, Edmond de Goncourt and Turgenev.

Together with other young writers of his own age—Paul Alexis, Henry Céard, Léon Hennique and J. K. Huysmans—Maupassant used to pass his Sundays at Zola's house at Médan. Thus when Zola and his circle published *Les Soirées de Médan* (April 1880), a collective volume of stories on the Franco-German War, Maupassant was a contributor to it. This book, an outspoken demonstration of naturalism in literature, provoked heated controversy. Maupassant's contribution was "Boule de suif." In this, a prostitute traveling by coach is companionably treated by her fellow passengers anxious to share her provisions of food until a German officer stops the coach and refuses to let it proceed until he has possessed her; the others then induce her to satisfy him, but ostracize her for the rest of the journey. Unanimously regarded as the best story in the book, it was described by some critics as a masterpiece. This result was the last satisfaction that Flaubert was to

have before his death (May 8, 1880).

The really triumphant success of "Boule de suif" was in Maupassant's mind when he later said that his passage through the world of letters was like that of a meteor. Unfortunately, however, he was thinking not only of his brilliant arrival in that world but also the painful end that he felt to be fast approaching him. In the period between "Boule de suif" and his collapse in 1891 he wrote enough to fill 30 books. *La Maison Tellier* (1881), a book of short stories on a variety of subjects, can be regarded as typical of his achievement as a whole, but in his novels as well as in his stories he was to show himself both versatile in his choice of themes and constant in his determination to present men and women just as he saw them in the manifold aspects of life. His concern was with *l'humble vérité*—words which he chose as the subtitle to his novel *Une Vie* (1883). This novel does in fact record what he had observed as a child, the little dramas of family relationships and the day-to-day preoccupations of real people, all drawn from life. A loyal disciple of Flaubert and of Zola, he presents his characters with strict objectivity, forgoing any expression of a personal judgment on them but noting always the word, the gesture or even the reticence that betrays the essential personality of each one and enhancing the effect by his description of the background against which they move. Conciseness, strength and the most rigorous economy are the characteristics of his art.

Collections of short stories and novels followed one another in quick succession until illness struck Maupassant down. Two years saw six new books of short stories: *Mademoiselle Fifi* (1883), *Contes de la bécasse* (1883), *Clair de lune*, *Les Soeurs Rondoh*, *Yvette* and *Miss Harriet* (all four 1884). Yet he knew that his family had a long history of neurosis and was himself subject to eye troubles and agonizing headaches. To distract himself from his anxiety he worked like a man possessed, took overviolent exercise and indulged in sensual pleasures that wore him out. Convinced that there was no escape for him, he sought both to enjoy all that he desired and to express all his potentialities, all that he had in him for posterity. He took stimulants and narcotics in excess.

As well as shorter pieces, Maupassant wrote full-length novels. *Bel-Ami* (1885), drawn from his observation of the Parisian world of sharp businessmen and cynical journalists, is a scathing satire on a society whose members let nothing stand in the way of their ambition to "get rich quick." *Bel-Ami*, the hero of the novel, is now a standard literary example of that attitude. When the sale of his books enabled him to buy a yacht, Maupassant named it "Bel Ami." *Sur l'eau* (1888) and *La Vie errante* (1890) are based on the cruises that he made in it in the Mediterranean.

Maupassant's later books of short stories include *Toine* (1886), *Le Horla* (1887), *Le Rosier de Madame Husson* (1888) and *L'Inutile Beauté* (1890). In "Le Horla" he made use of the theories that J. M. Charcot was putting forward in his lectures on hysteria and psychological disorders at the Salpêtrière hospital. These theories were at that moment receiving worldwide publicity, but Maupassant's use of them in "Le Horla" was mistakenly interpreted, after his subsequent confinement in a mental home, as reflecting the onset of his own madness. Four more novels also appeared: *Mont-Oriol* (1887), on the financing of a fashionable watering place; *Pierre et Jean* (1888), on a man's tragic jealousy of his half brother, the child of his mother's adultery; *Fort comme la mort* (1889); and *Notre coeur* (1890).

Maupassant's work is all thoroughly realistic. Nevertheless it reflects at many points his deep love for the Norman countryside and the sea. Some of his stories have such tragic power that Taine compared them to the plays of Aeschylus (for instance "Le Port" and "Le Champ d'oliviers"). He does in fact present his characters, poor people or rich bourgeois, as if they were the heroes of a Greek tragedy, their lives dominated by *ananké* or ironic necessity, crushed by the fate that they have dared to defy yet still struggling against it hopelessly. Such indeed was his own life, with his obstinate self-dedication to his work. Not until his pain had become unbearable did he give way to despair. Then, on Jan. 2, 1892, at Cannes, he tried unsuccessfully to cut his throat. Sent to A. E. Blanche's nursing home in Paris, he died

there on July 6, 1893, at the age of 42.

Because so many of his stories deal with madness, it has been alleged that Maupassant himself was already mad when he wrote them. Yet these stories are perfectly well balanced, and in them Maupassant treats madness as a doctor, not as a patient. Down to the last work that he wrote, all his work is characterized by a clarity of style that betrays no sign of mental disorder. The lucid purity of his French and the precision of his imagery are in fact the two features of his work which account for its success, especially outside France. In the discussion of novel writing which serves as a preface to *Pierre et Jean* he described the French language as a clear pool that affectation of style could never cloud. This is an unconscious definition of his own stylistic principles, a rejection of the "artistic" or "precious" style practised by Edmond de Goncourt (who never forgave him).

Maupassant's work is easily distinguished from that of other naturalist writers. He gives a true picture of the society of his time, in which every detail of background and behaviour is recognizable. Yet there is a universality in his view of mankind, and this explains how Benjamin Britten and the librettist Eric Crozier could turn "Le Rosier de Madame Husson," which Maupassant had set in the Vexin Normand, into *Albert Herring*, set in East Suffolk, by means of a few modifications of minor details (e.g., in the matter of local customs), without any change in the presentation of the characters. Likewise film after film has been made from Maupassant's novels and stories, each one topical and contemporary however much the world has changed since his time.

BIBLIOGRAPHY.—Collections of Maupassant's work include the Ollendorf edition, illustrated, 29 vol. (1900-04), the Conard edition, with preface by Pol Neveux, 29 vol. (1908-10); and the edition by René Dumesnil, 15 vol., including his letters and previously unpublished writings (1934-38). There is also a collected edition by A. M. Schmidt and G. Delaisement of his *Contes et nouvelles*, 2 vol. (1957), and of his *Romans*, 1 vol. (1959). See also *The Works of Guy de Maupassant*, Eng. trans. by M. Laurie, 10 vol. (1923-29), and the numerous English versions of individual works or smaller collections.

MAUPEOU, RENÉ NICOLAS CHARLES AUGUSTIN DE (1714-1792), the chancellor of France whose reform of the judicial system deprived the *parlements* of their political powers, was born in Paris on Feb. 25, 1714, the eldest son of René Charles de Maupeou. His father, who was premier president of the *parlement* of Paris from 1743 to 1757, was appointed keeper of the seals in 1763 and became chancellor on Sept. 15, 1768, but resigned within 24 hours. Then René Nicolas, who had himself been made premier president in 1763, took office in his turn as chancellor.

At this time the French *parlements* seemed to have reached the height of their power, exercising a close supervision and control over the royal finances, influencing the course of the government's religious policy and presuming to interfere even in the administration of the separate provinces. After imposing the recall of the duc d'Aiguillon from the military governorship of Brittany in view of the affair of La Chalotais, however, the *parlement* of Paris overplayed its hand by attempting to procure his prosecution at law. The disgrace of the duc de Choiseul, who had protected the *parlements*, in 1770 and the return to favour of the duc d'Aiguillon as foreign minister in 1771 led to the formation of a strongly authoritarian government determined to reassert the royal authority.

After further conflicts during which the magistrates of the *parlement* of Paris had defied a *lit de justice* and had called a judicial strike, Maupeou resorted to force. On the night of Jan. 19, 1771, musketeers delivered to each judge of the Paris *parlement* a *lettre de cachet*, ordering him to declare whether or not he

would resume his judicial duties. When nearly all refused, 130 of them were exiled to remote places in the provinces and deprived, without compensation, of their offices. On Feb. 23, 1771, Maupeou established by decree six superior councils to exercise in their respective areas the judicial authority formerly possessed by the *parlement*. Part of the latter, the *grand conseil* (later known as the *parlement Maupeou*), was however preserved to act as a special tribunal for crown cases and to exercise the right of legitimate remonstrance, i.e., against the form but not the substance of royal legislation. Soon afterward both the *cour des aides* (dealing with fiscal cases) and the *châtelet*, or central criminal court, were abolished. Louis XV prevented Maupeou from suppressing the provincial *parlements*.

In proposing these reforms, Maupeou implied that they amounted only to administrative changes designed to restrict the overgrown jurisdiction of the *parlement* of Paris, to abolish the sale of judicial offices by the establishment of magistrates appointed by the crown and to remove the abuse of judicial bribes (*épices*) by the payment of fixed salaries to the judges. The significance of the reforms, however, was mainly political, for they challenged the pretensions of the *parlement* of Paris to act as the substitute for the estates-general, withdrew the power of vetoing royal legislation and rebutted the claim of the provincial *parlements* to the character of a unified corporation within the state. Designed to uphold the sovereign authority of the monarchy against quasi-judicial criticism, the reforms were in fact carried out by a *coup d'état*—but one which would have paved the way for an enlightened despotism in France, unrestrained by the reactionary opposition of hereditary magistrates.

Public opinion reacted strongly both against the manner of the coup and against the alleged despotism of Maupeou. Jansenists and Gallicans detected in the reforms the influence of the Jesuits; the provincial nobility feared the loss of its privileges and local liberties; and, with the exception of Voltaire and Condorcet, the *philosophes* were also critical, for they feared that the masses would accept the leadership of the exiled magistrates. Yet by the end of Louis XV's reign the new system was operating successfully. With the accession of Louis XVI in 1774 a series of ministerial changes occurred. Maupeou fell from power (though he remained chancellor in theory), and the *parlement* of Paris was restored to its former powers and privileges. Maupeou died in retirement at Thuit (Eure) on July 29, 1792.

MAUPERTUIS, PIERRE LOUIS MOREAU DE (1698-1759), French astronomer and mathematician, best known for his principle of least action, was born at St. Malo on Sept. 28, 1698, and died at Basel, Switz., on July 27, 1759. He became a member of the Académie des Sciences at Paris in 1731, and the following year he introduced into France the Newtonian doctrine of gravitation. In 1736 Maupertuis led an expedition to Lapland to measure the length of a degree along the meridian, thereby verifying the Newtonian view of the earth as an oblate spheroid—a sphere flattened at the poles. Called to Berlin, he became a member of the Academy of Sciences there in 1741 and served as president from 1745 to 1753.

Maupertuis contributed mathematical papers to the *Mémoires* of the Académie des Sciences of Paris and published more than half a dozen books on geography, astronomy and cosmology. In 1744, enunciating the principle of least action, he claimed that the operations of nature conform to a rule of economy in which action, defined by $\int mv ds$, is a minimum. The chevalier d'Arcy, however, pointed to cases in which action is a maximum rather than a minimum; and Samuel Koenig accused Maupertuis of plagiarism from Leibniz. In the ensuing polemic Euler came to the support of Maupertuis; but Voltaire, once his proselyte, satirized the "earth flattener" so mercilessly that Maupertuis, a favourite of Frederick the Great, left Berlin for Paris in 1753.

The *Oeuvres* appeared at Dresden in 1752, at Berlin in 1753, and

in new four-volume editions at Lyons in 1756 and 1768.

For bio-bibliographical details see Pierre Brunet, *Maupertuis, Pœuvre et sa place dans la pensée scientifique et philosophique du XVIII^e siècle* (1929). (C. B. Br.)

MAURA Y MONTANER, ANTONIO (1853–1925), Spanish statesman, five times prime minister, was born at Palma de Mallorca on May 2, 1853. Graduating in law from the University of Madrid, he became a successful advocate: a native Catalan-speaker, he made himself a master of oratory in Castilian Spanish. Deputy for Palma in the *Cortes* of 1881, he attached himself to P. M. Sagasta's Liberal party. Appointed minister for the colonies in Dec. 1892, he resigned when his proposals to grant autonomy to Cuba came to nothing (1894), but resumed office as minister of justice for a few weeks early in 1895. Progressively estranged from Sagasta, he became the leader of a distinct group, which he merged with the Conservative party in 1902. From Dec. 1902 to Oct. 1903 he was minister of the interior.

Maura's first period as prime minister (Dec. 1903–Dec. 1904) was troubled by opposition to his financial and ecclesiastical policy. Appointed prime minister again in Jan. 1907, he embarked on that program of reform or "revolution from above" (*desde arriba*) or "from the government" (*desde el gobierno*) for which he had called during the Spanish-American War of 1898. He sought to transform local administration by breaking the power of the *caciques* (bosses) and introduced laws to make education compulsory, to set up industrial tribunals and to strengthen the economy. He had also worked to uphold Spanish interests in Morocco, but the conscription of troops to defend Melilla against the Riff tribesmen provoked disorders in Barcelona in July 1909; and the savage repression of these disorders, followed by military reverses in Morocco, led to Maura's fall from power (Oct. 1909). He resigned the leadership of the Conservatives in 1913, but headed three more short-lived governments in times of crisis (March–Nov. 1918; April–July 1919; Aug. 1921–March 1922). A steadfast adherent of constitutional practice, he deprecated Miguel Primo de Rivera's seizure of power by a military coup in 1923. Maura died at Torreldones, near Madrid, on Dec. 13, 1925. See also SPAIN.

MAUREPAS, JEAN FRÉDÉRIC PHÉLYPEAUX, COMTE DE (1701–1781), French statesman, was born at Versailles on July 9, 1701, the eldest son of Jérôme de Pontchartrain, one of the secretaries of state. In 1715 Pontchartrain's incapacity prompted the duc de Saint-Simon to suggest that the title and emoluments of his office should be transferred to his 14-year-old son and its functions performed by his relative the marquis de La Vrillière, who was himself also a secretary of state (d. 1725). In 1718, on marrying La Vrillière's daughter, Maurepas was given formal control of the department of the king's household; and in 1723 he was assigned the marine department also.

As an administrator the comte de Maurepas proved himself intelligent, disinterested and active, remaining in office until 1749, when he was disgraced by Louis XV as a result of a personal quarrel with Mme de Pompadour. He was recalled from exile by Louis XVI on his accession in 1774, in the capacity of chief confidential adviser without portfolio. It was very largely Maurepas who was responsible for the restoration to the *parlements* of their former political powers, of which they had been deprived in 1771. This act, which was to compromise the prospects of effective fiscal and administrative reform during the remainder of the *ancien régime*, may be attributed to Maurepas' prejudices in favour of the judicial authority imbibed from his grandfather, who had been chancellor under Louis XIV, to his spiteful desire to destroy the chief political innovation of Louis XV's reign and to his shortsighted bid for popularity.

Able, shrewd and experienced, Maurepas was cynical in his use of political power and greatly accelerated the decline in the monarchy's fortunes by his abandonment of Turgot in 1776 and of Necker in 1781, when those reforming ministers threatened to challenge his ascendancy over the king. He died at Versailles on Nov. 21, 1781. (A. Gn.)

MAURER, GEORG LUDWIG, RITTER VON (1790–1872), German legal historian and statesman, one of the 19th-century

German scholars inspired by the rising tide of nationalism both to investigate his country's past and to take an active part in its politics. Maurer was born at Erpolzheim near Dürkheim on Nov. 2, 1790, but spent his youth near Heidelberg and attended the university there.

The romantic movement which inspired such scholars as Jacob Grimm and Friedrich von Savigny drove him to inquire into early German institutions. In 1824 he published his *Geschichte des altgermanischen . . . öffentlich-mündlich Gerichtsverfahrens*, a standard though superseded work. In 1826 he became professor of German civil law and legal history at Munich. His most considerable work consists of 12 monographs on German local government (*Geschichte der deutschen Gemeindeverfassung*, 1854–71). Though defective in detail it is rich in material and ideas.

Maurer's political life continued meanwhile. After holding a number of official legal posts he was appointed a member of the Bavarian *Staatsrat* in 1829. When Prince Otto of Bavaria became king of Greece in 1832, Maurer was made one of his council of regency and until his recall in 1834 he worked at the task of giving Greece a revised penal code and civil procedure. He published a book on Greece in 1835. After the fall of Karl von Abel in 1847 he was for a few months Bavarian chief minister. He died at Munich on May 9, 1872.

See K. T. von Heigel, *Denkwürdigkeiten des . . . G. L. von Maurer* (1903).

MAURETANIA, the Roman name of part of Africa north of the Atlas mountains and the Sahara, comprising parts of modern Morocco and Algeria. Its early inhabitants of Berber stock were divided into numerous tribes collectively referred to by the Romans as *Mauri*, and were mostly seminomadic pastoralists. The Mulucha (Moulouya) river was the boundary between the Mauri in a restricted sense and another tribal group to the east, the Masaesyli. From the 6th century B.C. Phoenicians and Carthaginians settled at many points on the Mediterranean and Atlantic coasts, though their civilization spread only slowly into the interior. Mauretanian history really begins with the Punic Wars. The Masaesyli became part of Masinissa's Numidian kingdom in 203 B.C. after the defeat of its ruler Syphax, an ally of Carthage against Rome. Between 108 and 105 B.C. Bocchus, who ruled west of the Mulucha, hesitated between an alliance with Jugurtha (q.v.) or the Romans, finally siding with the latter, to be rewarded with an extension of territory eastward. It was Roman policy to dominate such a vast, difficult and ill-defined area through loyal client kings (see *Bocchus*; *Juba*). The last ruler of all Mauretanian was Ptolemy, who was executed by Caligula in A.D. 39 or 40 for reasons unknown. After the suppression of a subsequent revolt of the Mauri, Mauretanian was provincialized; it was soon divided into two provinces, Mauretanian Tingitana, with its capital at Tingis (Tangier) west of the Mulucha, and Mauretanian Caesariensis, with its capital at Caesarea (Cherchel) between the Mulucha and Ampsaga (Wadi el Kebir). Both were governed by officials of equestrian rank and only auxiliary units were stationed in them. Wars and revolts are recorded on a number of occasions throughout the imperial period and though almost all were of a minor and local character, it is clear that in the extensive mountain ranges and in the desert areas, where the nomads paid little attention to frontiers, Roman rule was never fully accepted. Mauretanians were good military material and were used by the Romans in both Africa and other parts of the empire, being particularly effective as light cavalry. They had little bent for city life, and the tribal units were not broken up by the Romans, who continued to recognize the chiefs, generally supervising them by officials called *praefecti*. A few native Mauretanians achieved prominence in the empire, for example Lusius Quietus, a tribal chief who became one of Trajan's best generals. There were seven *coloniae civium Romanorum* in Tingitana and eleven in Caesariensis and a number of *municipia*, but the influence of Roman civilization was restricted to points on the coast, river valleys like that of the Chinalaph (Chéliff) and the plains round Sitifis (Sétif).

Serious revolts beginning in 297 required the presence of the emperor Maximian and parts of both provinces were permanently given up. In Diocletian's reorganization a new province, Maure-

tania Sitifensis, was formed out of the eastern part of Caesariensis. When the Vandals arrived in Africa in 429 much of Mauretania became virtually independent and Mauretanians participated as allies in Vandal campaigns against Rome and Italy. The Byzantine reconquest of Africa after 533 extended to only a small part of Mauretania where little now remained of Roman influence except Christianity, which had spread rapidly in the 4th and 5th centuries but which was extinguished when the Arabs finally overcame determined Mauretanian resistance.

MAURIAC, FRANÇOIS CHARLES (1885—), French novelist and winner of the Nobel prize for literature in 1952, was born in Bordeaux on Oct. 11, 1885. His family had its roots deep in this region, which was to provide the framework and essential atmosphere for most of his stories. The circumstances of his childhood—strongly marked by Catholic influences which proved lasting—are admirably described in *Commencements d'une vie* (1932). He studied at the University of Bordeaux and in 1906 entered the Paris École des Chartes for a short period. His literary career began in 1909 with a volume of poems entitled *Les Mains jointes*, which brought him to the notice of Maurice Barrès. (See *La Rencontre avec Barrès*, 1945.)

Mauriac's first novels were *L'Enfant chargé de chaînes* (1913) and *La Robe prétexte* (1914), followed by *La Chair et le sang* (1920) and *Préséances* (1921). These stories, especially the first two, showed his technique as still uncertain, but they gave indications, particularly *La Chair et le sang*, of his insight into some of those troubled human relationships which he later depicted so forcibly. They deal with themes which constantly recur in his writings: the strains of adolescence, religious and emotional conflicts, the narrow materialism of commercial and middle-class life in his own part of provincial France. *Le Baiser au lépreux* (1922), describing a tragic incompatibility between husband and wife, established Mauriac as a major novelist. He showed increasing mastery in *Génitrix* (1923), a grim story of obsessive maternal affection, *Le Désert de l'amour* (1925; grand prix du roman of the Académie Française) and *Thérèse Desqueyroux* (1927). The heroine of this novel, a woman driven to attempt the murder of her husband for motives she does not fully comprehend, reappears in *La Fin de la nuit* (1935) and in two of the short stories contained in *Plongées* (1938). *Le Noeud de vipères* (1932) is often considered Mauriac's masterpiece. It depicts an old man's rancorous enmity toward his family and his eventual change of heart.

In 1933 Mauriac became a member of the Académie Française. His subsequent novels included *Le Mystère Frontenac* (1933), a much less sombre story than most of his works, *Les Anges noirs* (1936), *Les Chemins de la mer* (1939) and *La Pharissienne* (1941), a scathing analysis of religious hypocrisy and the desire for domination. Some shorter stories, published after World War II, met with unequal success; *Le Sagouin* (1951); *Galigai* (1952); *L'Âneau* (1954).

In 1938 Mauriac had begun what seemed likely to be a notable career as a dramatist with *Asmodée*, a further study of religious hypocrisy. This was followed by *Les Mal Aimés* (1945) but *Le Passage du Malin* (1947) was less successful.

Mauriac was highly sensitive to criticism and anxious to justify himself as a novelist. *Le Roman* (1928), *Le Romancier et ses personnages* (1933) and the five volumes of his *Journal* (1934–53) say much about his intentions and methods. The *Journal* is a work of outstanding interest, which also records his reactions to moral and contemporary problems and his reflections on literature and music. (See also *Mémoires intérieurs*, 1959.)

From about 1923 to 1930 Mauriac went through a period of religious disquiet. He was faced with two problems: as an individual he had to work out his faith anew; as an artist he had to reconcile his duty as a novelist with his obligations as a Catholic—namely how to portray the evil in human nature without putting temptation into the minds of his readers. These conflicts and the convictions that emerged are recorded in *Dieu et Mammon* (1929) and *Souffrances et bonheur du chrétien* (1931). His preoccupation with religious themes found constant expression, for instance

in his *Vie de Jésus* (1936), his biographies of St. Margaret of Cortona, Racine and Pascal and the essays on literary topics contained in *Mes Grands Hommes* (1949). As a creative writer he was first and foremost an observer of mankind in the light of eternity. The doctrines of grace and redemption underlie his delineation of human passions, frustrations and weaknesses, particularly sensuality, avarice, jealousy and pride. His characters lead narrowly circumscribed lives, preoccupied with their own problems and little affected by the outside world; their relations with each other, their indwelling upon themselves and the predestined patterns of their lives are all recorded with singular intensity and concentration.

Mauriac was also prominent as a polemical writer. He intervened vigorously in the ideological conflicts of the 1930s, condemning totalitarianism in all its forms and denouncing fascist excesses in Ethiopia and Spain. In World War II, during the occupation of France, he worked with the writers of the Resistance. *Le Cahier noir*, published in the clandestine *Éditions de minuit* in 1943 under the pen name of Forez, was a declaration of faith in fundamental human values. After the war he became increasingly engaged in political discussion, first as an editorial writer for the *Figaro* and then as a contributor to *L'Express*.

In 1946, with *A Woman of the Pharisees* (*La Pharissienne*), Gerard Hopkins began a complete translation into English of Mauriac's novels.

MAURICE (MAURITIUS), SAINT (d. c. 286), an early Christian martyr. The oldest form of his story is found in the *Passio Martyrum Acaunensium*, ascribed to Eucherius, bishop of Lyons, c. 450, who relates how the Theban legion (from the Thebaid in Egypt) commanded by Mauritius was sent to north Italy to reinforce the army of Maximian. Maximian wished to use them in persecuting the Christians, but as they themselves were of this faith, they refused, and for this, after having been twice decimated, the legion was exterminated at Octodurum (modern Martigny, in Valais canton, Switz.).

Critical study of the legend was stimulated by excavations carried out at St. Maurice (Celtic Agaunum, in Valais canton near Martigny) from 1944 to 1949. In 1956 appeared D. van Berchem's thorough analysis of Eucherius' *Passio*, mentioned above. Since this 5th-century bishop gives as his ultimate source the oral account of Theodore, 4th-century bishop of Octodurum (who signed the decrees of the Council of Aquileia in 381 and to whom reference again is made in 389 or 390), it is with this Theodore that Berchem is especially concerned. He believes him to have been an oriental who brought from his native east to the west the legend of St. Maurice of Apamea, a military saint, who suffered martyrdom together with the 70 soldiers under his command. Theodore may have brought relics of these martyrs with him to the west or, in an age when discovery of the relics of martyrs was not uncommon, he may have transferred the legend to the remains of several bodies which he had found and over which he dedicated a basilica. The explanation is ingenious, and though it remains pure hypothesis, all future work must begin with Berchem's keen criticism of the legend. As a specialist in the history of the Roman army, he showed that if soldiers were martyred at Octodurum they were not Thebans and certainly not a legion, for two of their officers—Mauritius, a *primicerius*, and Candidus, a *senator militum*—have the titles of cavalry officers, whereas a legion was a formation of infantrymen.

The cult of St. Maurice and the Theban legion is found in Switzerland (where two places bear the name in Valais, besides St. Moritz in Grisons), along the Rhine and in north Italy. The foundation of the abbey of St. Maurice in Valais is usually ascribed to Sigismund of Burgundy (515). Relics of the saint are preserved there and at Brieg and Turin. The feast of St. Maurice and his companions is celebrated on Sept. 22.

An elaborate bibliography covering the older literature, which includes many discussions of the interpolated version or versions of Eucherius' *Passio* and many studies of the diffusion of the cult of these martyrs, is to be found appended to H. Leclercq's article, "Maurice d'Againe (Saint)," in the *Dictionnaire d'Archéologie chrétienne et de liturgie*, vol. x, col. 2699–2729 (1932).

(AM. S.)

MAURICE (MAURICIUS FLAVIUS TIBERIUS) (c. 539–602), Byzantine emperor from 582 to 602, was a Cappadocian. A soldier of distinction, as *comes excubitorum* he directed the Persian war in the last years of Tiberius II's reign (578–582). On Aug. 5, 582, the dying Tiberius made him Caesar, and on Aug. 13, 582, crowned him emperor and betrothed him to his daughter Constantia. Maurice succeeded to an empty exchequer and made himself unpopular by his policy of retrenchment. In the east the Persian war continued with varying success until a revolution in Persia enabled Maurice to restore the exiled Khosrau (Chosroes) II (591) on condition that he ceded Persarmenia and East Mesopotamia with Daras and Martyropolis.

From 592 onward campaigns in the Balkans and beyond the Danube frontier were directed against the Avars, and also the Slavs who were ravaging the Balkans and Greece and settling in these provinces. Though fully occupied in the north and east, Maurice did not abandon the west. He created the exarchates of Ravenna and Carthage in which the governor (exarch) was a military commander also having civil authority, thus foreshadowing the 7th-century system of themes. His will drawn up in 597 bequeathed Rome, Italy and the western islands to his second son, showing that he regarded the west as an integral part of the empire. Maurice's severe military discipline and his strict economy caused a revolt amongst the troops on the Danube which spread to the factions in the capital. Maurice fled to Asia Minor and the army's spokesman Phocas was proclaimed emperor (602). Shortly afterward Maurice and his sons were executed.

(J. M. HY.)

MAURICE (1567–1625), prince of Orange and military leader of the United Provinces of the Netherlands in their war of independence against Spain, was born at Dillenburg on Nov. 13, 1567, the son of William I the Silent, prince of Orange, by his second wife, Anna, only daughter of Maurice of Saxony. After studies at Heidelberg he went to the Netherlands in 1577 and stayed with his father at Breda and at Antwerp. At the instance and partly at the expense of the estates of Holland he was sent to Leiden (1583) to read mathematics and classics. After the assassination of his father (July 1584) he was appointed president of the council of state of the United Provinces and in Nov. 1585 succeeded his father as stadholder of Holland and Zeeland. He was allowed by the estates of Holland in 1586 to call himself "born prince of Orange" but he did not rightly succeed to the princely title till his elder half brother Philip William, who was in Spain from 1566 to 1596, died childless in 1618.

Maurice began to play a rôle of importance when the earl of Leicester left the Netherlands at the end of 1587. He became also stadholder of Utrecht and Overijssel in 1590 and of Gelderland in 1591 and was moreover admiral general and captain general of the forces paid by the provinces of which he was stadholder. He reorganized the army in a scientific way, making use of Roman military principles as well as of his mathematical knowledge (he was himself a specialist in siege warfare); and he enjoined his engineers and officers to study at his old university of Leiden. His revival of the art of war made the Dutch army the most modern in Europe and attracted much attention. In the years 1590–98 he and his cousin, William Louis, stadholder of Friesland, who was his close collaborator, drove the Spanish army out of their strongholds in the northern and eastern provinces (for details see

NETHERLANDS, THE: *History*). After 1598, however, Maurice was less successful; he was not much interested in conquering the southern Netherlands, and in this respect (as in many others) his attitude differed fundamentally from his father's. When the advocate of Holland, Johan van Oldenbarnevelt (*q.v.*) organized the attempt to carry the war southward, Maurice did not really approve of it; and his military triumph at the battle of Nieuwpoort in West Flanders, where he beat the Spaniards under the archduke Albert in the open field (July 2, 1600), remained a fruitless victory.

Tension between Maurice and Oldenbarnevelt grew up when Oldenbarnevelt, after England had made peace with Spain (1604), saw that the war had lost its purpose and began negotiations with the southern Netherlands. The 12 years' truce which was finally agreed upon in 1609 was bitterly opposed by Maurice, who was afraid that the army would be weakened and the interests of the house of Orange neglected. When the quarrel between Arminians and Gomarists within the Reformed Church seemed about to turn into civil war, Maurice, although ignorant about doctrinal questions, in 1617 took the Gomarist or extreme Calvinist side against Oldenbarnevelt, who supported the Arminians. He finally had Oldenbarnevelt arrested (1618) and executed (1619).

Maurice, who became stadholder of Groningen in 1620, made little use of his victory over Oldenbarnevelt's party. His most important decision after 1619 was his refusal to extend the 12 years' truce in 1621, but the war that he thus resumed was unsuccessful for him. He fell a victim to a liver ailment and died, a disappointed man, in The Hague on April 23, 1625. Unmarried, he had had seven illegitimate children.

(E. H. K.)

MAURICE (1521–1553), elector of Saxony from 1547, a dynamic, versatile and cynical prince who turned the troubles of the Reformation in Germany to his own great advantage, was born on March 21, 1521, at Freiberg in ducal Saxony (Meissen), the son of the future duke Henry, of the Albertine branch of the Wettin dynasty. Henry's elder brother George, a stern Catholic who ruled the duchy from Dresden, tried to exclude Henry from the succession unless he would renounce Lutheranism; but on George's death in 1539 Henry promptly sponsored the Reformation in the Albertine lands and soon won the approval of the territorial estates. As well as these conflicting examples, Maurice grew up to know both the classical Lutheranism of Wittenberg and the universalistic outlook of the Holy Roman emperor Charles V's court; and his marriage, early in 1541, to Agnes of Hesse linked him also with the Protestant activism of her father, the landgrave Philip (see PHILIP the Magnanimous).

Maurice became duke of Saxony on Henry's death in 1541. At this time Philip of Hesse for personal reasons was coming to terms with Charles V by departing from the extreme position that he had originally taken in the Protestant princes' League of Schmalkalden; and this consideration, together with the advice of Georg von Carlowitz, a Catholic exponent of compromise who had served George and Henry alike, was one of the reasons why Maurice for the next four years pursued a noncommittal policy between the emperor and the league (see GERMANY: *History*). Another consideration, however, was that, apart from Philip, the dominant prince in the league was the elector of Saxony, John Frederick I (*q.v.*), head of the Ernestine Wettins, who was now beginning to interfere aggressively in ecclesiastical matters affecting Albertine spheres of influence. Accordingly Maurice assisted Charles V against the Turks in 1542, against Cleves in 1543, and against France in 1544, but supported the League of Schmalkalden against Henry II of Brunswick-Wolfenbüttel in 1545. In June 1546, however, at Regensburg, Charles V won Maurice's good will for his projected war against the league; and when Charles in October had formally agreed to transfer the Saxon electoral dignity to him, Maurice invaded John Frederick's lands. A counterattack drove Maurice from most of his own Albertine territory early in 1547,

but Charles then marched to his help. John Frederick was captured at the battle of Mühldorf (April 24) and ceded the electoral dignity and much territory to Maurice by the capitulation of Wittenberg (May).

Since Maurice was reluctant to accept the Augsburg Interim of 1548 for the temporary settlement of the religious question, the so-called Leipzig Interim, a mitigated version, was negotiated for Saxony. Maurice, however, soon began to nurse grievances against the emperor. Personally he resented the imprisonment of Philip of Hesse, who had surrendered at the end of the Schmalkaldic War only on the strength of Maurice's undertaking that he (Philip) should not be imprisoned; and generally he objected to Charles V's "Spanish" attempt to "enslave" the German princes. He therefore sought to plot a revolt. Commissioned to enforce the ban of the empire against Lutheran Magdeburg, which was still standing out against the Interim, he seized the pretext for raising an army; and after the reduction of Magdeburg (Nov. 1550), which he treated very leniently but kept under his control, some embittered Protestant princes, who had hitherto regarded him as a Judas, fell in with his plans. In Jan. 1552 the treaty of Chambord was concluded between the conspiring German princes and France.

Hostilities began in March 1552. The rebels overran southern Germany, Maurice took the Ehrenberg pass in May, the emperor fled from Innsbruck to Villach in Carinthia, and the Council of Trent dispersed itself. Though Charles V refused a definitive settlement of the religious issue before the next meeting of the *Reichstag*, Maurice through negotiation with the emperor's brother Ferdinand I obtained the armistice of Passau (Aug. 1552), which provisionally guaranteed the Lutheran position, granted the political claims of the princes and secured the liberty of Philip.

While the emperor marched against the French invaders of Lorraine, Maurice went to fight for Ferdinand against the Turks in Hungary. Returning to Germany, he took up arms against his former ally Albert Alcibiades of Brandenburg-Kulmbach, who had rejected the armistice of Passau. At Sievershausen, on July 9, 1553, Albert Alcibiades was defeated, but Maurice himself was killed.

MAURICE, (JOHN) FREDERICK DENISON (1805–1872), one of the most outstanding theologians and liberal thinkers of the Church of England in the 19th century, was born at Normanston, Suffolk, on Aug. 29, 1805, the son of a Unitarian minister. The family became sharply divided on matters of religious belief, and this early experience of disunity was one of the causes of Maurice's lifelong concern for unity and reconciliation among men. In 1823 he entered Trinity college, Cambridge, transferring later to Trinity hall, and in 1827 obtained a first class in civil law. At this time he was greatly influenced by the writings of the poet Coleridge.

After several years in London working as a writer and journalist, Maurice decided to seek ordination in the Church of England. In 1830 he went to Exeter college, Oxford, where he was baptized in 1831. He was ordained in 1834 and, after a brief curacy, became chaplain to Guy's hospital in London. In 1840 he was appointed professor of English history and literature at the recently founded King's college, London, and in 1846 he became professor of divinity there. These chairs he held until 1853, when he was deprived of them for supposedly unorthodox views on eternal punishment. He remained in London as chaplain of Lincoln's Inn and from 1860 to 1869 was incumbent of St. Peter's, Vere street. Throughout the period he exercised an important influence in the political and literary world of London, by preaching and writing and, above all, by the nobility of his character. In 1866 Maurice was appointed professor of moral philosophy at Cambridge university and from 1870 to 1872 was also incumbent of St. Edward's in Cambridge. He died in Cambridge on April 1, 1872.

Maurice was impatient of all the party "orthodoxies" of his day, which seemed to him too narrow to match the breadth and inclusiveness of the Christian revelation. In a more profound sense his own theology was deeply orthodox and biblical, but marked by a great liberality of outlook which brought him into conflict with many of the received opinions of Victorian religion, as, for example, in his controversy with both evangelicals and high

churchmen about the doctrine of atonement. In his great work *The Kingdom of Christ* (1837) he sought to show the possibility of drawing out the positive elements in all the different Christian traditions and of bringing them together into one catholic whole. For him, theology was to be a source of unity, not division, and its scope was the whole of man's personal and social nature. Hence, both in his writing and in his action he frequently went beyond the narrowly ecclesiastical sphere.

Maurice was closely connected with the beginnings of Christian socialism (*q.v.*) and with the foundation of Queen's college, London, for the education of women (1848). He planned and became the first principal of the Working Men's college in London (1854).

Maurice was a voluminous writer, but his style lacks clarity and conciseness and in his own day he had the reputation of being a cloudy thinker. Besides *The Kingdom of Christ* his most notable works are *Moral and Metaphysical Philosophy* (1848), *Theological Essays* (1853) and *The Doctrine of Sacrifice* (1854). Later study of his work has revealed a writer of genuinely prophetic insight and remarkable creative power.

MAURIENNE, a high Alpine valley, about 80 mi. long, in southeastern France, drained by the Arc river, tributary of the Isère. Lying behind the central crystalline mountains of the Savoie Alps, it was for long extremely isolated, but modern communications approaching the Col du Mont Cenis (*q.v.*) crossing from France to Italy have opened it to the outside world. Since 1869 it has been followed by the railway as far as Modane (3,200 ft.), whence the line turns south toward the tunnel. The road continues higher up the valley to Lanslebourg (4,330 ft.) at the foot of the Mont Cenis pass and a valley road continues past Bonneval, as part of the Route des Alpes, to the Col de l'Iseran, which leads into the head of the Isère valley. Lower down the Maurienne, the Route des Alpes leaves the valley line at St. Michel to climb south toward the Col du Galibier via Valloire.

The Arc river crosses transversely the grain of varied, narrow outcrops of heavily folded and overthrust rocks that constitute the internal zone of the Alpine system; the Maurienne is a succession of narrow, wild gorges cut through rock bars, and more open basins. In such a basin, at 1,896 ft., lies the chief market centre, St. Jean de Maurienne, with a medieval cathedral. Sheltered by the surrounding wet, snowy mountains, the Maurienne is itself relatively dry with sunny summers, but winters are severe with a long period of snow cover. Altitude limits of vegetation, crops and settlement are remarkably high. The vine has been grown up to 3,500 ft. and hardy crops to 7,000 ft. The highest hamlet, Averole, lies near that height. There are rich forests on the high mountain slopes and fine Alpine pastures toward the snow line. The shady north-facing slopes are often deserted and clothed with continuous forest, but the notches of side valleys provide shoulders for chalets at a variety of altitudes, and a pastoral economy prevails, with cultivation of fodder crops on gently sloping land at lower levels and seasonal grazing of the alps. The elaborate up-and-down seasonal movements of cattle and herdsmen are much less practised than formerly, and more specialized dairying has become general. There are a few workings of anthracite, but the chief industrial resource is water power. The torrents that gash the valley sides have been harnessed in many places to drive turbines and, although most of the hydroelectric power is exported, some electrometallurgical and electrochemical industries have been established along the route, for example at Modane and Pontamafrey. (Ar. E. S.)

MAURISTS (CONGREGATION OF ST. MAUR), a congregation of French Benedictine monks (*see* BENEDICTINES), founded in 1618, whose patron, St. Maurus, according to legend introduced the Benedictine rule to France. The name is commonly restricted to those devoted to learned work. Their peculiar characteristics were due to Dom Gregory Tarrisse (1575–1648), the first president, who desired to make literary work a distinguishing feature; he organized schools of training and set up their headquarters,

which soon became a rendezvous for all the scholars of the *grand siècle*, at St. Germain-des-Prés (Paris). As the monks professed for the congregation, not the individual house, promising students could be selected and work apportioned by the superiors. Tarrisse found in Luc d'Achery (1609–85) an excellent organizer of his designs. D'Achery built up a great library and outlined a program, which he himself began to execute. He also recognized the genius of Jean Mabillon (*q.v.*), the greatest of the Maurists. The golden age lay between the arrival of Mabillon (1664) and the death (1741) of Bernard de Montfaucon (*q.v.*). Mabillon, prince of monastic historians, the creator of the modern discipline of paleography and diplomatic with his magisterial *De re diplomatica* (1681), who was in himself a man of admirable integrity and exemplary piety, is also remembered for his edition of St. Bernard, his publication of the *Lives* of Benedictine saints and his *Annals* of monastic history from Benedict to Bernard. Montfaucon, a genial, indefatigable worker of a less spiritual mold, who did for Greek paleography what Mabillon had done for Latin, produced editions of Athanasius and Chrysostom and in his last years two works which had an immense vogue and remained as models: an encyclopaedic history of the ancient world and an illustrated "social" history of medieval France. Meanwhile Mabillon and his disciples Thierry Ruinart (d. 1709) and Edmond Martène (d. 1739) had done pioneer work on ancient liturgy and ritual and had commented upon the rule of St. Benedict; other companions had produced a complete edition of St. Augustine. In the 18th century great projects of every kind were begun: a history of the crusades; a literary history of France, the *Gallia Christiana*; a basic work of chronology, *L'Art de vérifier les dates*—to say nothing of numberless regional and civic histories.

The Maurists as a group were, and have remained, without a parallel in the annals of scholarship both for the bulk of work achieved and the uniform level of excellence attained. Both as editors and historians they excelled, and many of their texts remain the best available; they were pioneers in critical medieval history and their work has attached the adjective "learned" to the Benedictines. The congregation was suppressed during the French Revolution in 1789.

See J. Baudot, in A. Vacant (ed.), *Dictionnaire de théologie catholique*, vol. x (1928); M. D. Knowles, "The Maurists," *Transactions of the Royal Historical Society*, 5th series, vol. 9 (1959). (M. D. K.)

MAURITANIA, ISLAMIC REPUBLIC OF (RÉPUBLIQUE ISLAMIQUE DE MAURITANIE), an independent republic on the west coast of Africa, is bounded by the Atlantic ocean and Spanish Sahara on the west, Algeria on the northeast, Mali on the east and south and Senegal on the south. A former territory of French West Africa, it gained its full independence in 1960. Area 419,229 sq.mi. Pop. (1961 est.) 792,019. The capital is Nouakchott (*q.v.*).

Physical Features.—Mauritania represents the western part of the Sahara, which is desert, but desert mitigated by the proximity of the cool ocean waters. The crystalline bed is partially concealed by dunes, some formed by the trade winds and shifting, others, in the Trarza and Brakna region toward Senegal, more or less stable. This base disappears beneath plateaus of primary sandstone near Spanish Sahara and particularly in the southeast. The steep edges of these plateaus form the principal relief. Harmattan winds persist in the interior, and even the trade winds, felt along the coast, bring little rain. The moistest part of the country is the extreme southeast. Sélibaby averages about 26 in. of rainfall annually. Temperatures and humidity vary widely, both seasonally and daily. The coast is broken by promontories oriented in a southwesterly direction (e.g., Cape Blanc, which forms the bay of Port Étienne) and is sandy in the south. Port Étienne, however, is the only port. (J. D.)

People.—The valley of the Senegal river in the south, which forms the boundary between Mauritania and Senegal, is inhabited by Negro agricultural tribes, such as the Tukulor (Toucouleur) and the Sarakole (or Soninke), with Fulani (Peul) cattle breeders. The rest of the country is peopled by Moors, pastoral nomads of Berber and Arab stock, who are mainly fair-skinned though mixed with Negro blood in the more depressed classes (freed slaves, serv-

ants, and Haratin or cultivators). They are Muslims and mostly Arabic-speaking. The southern tribes (of the Trarza, Brakna and Kunta regions) practise short-distance nomadism, to the river and back, with cattle, sheep and goats. The northern tribes (Regeibat) raise mainly camels and practise long-distance nomadism. The inhabitants of the oases are Negroes.

History.—Numerous discoveries of Acheulian and Neolithic remains have been made in the north.

Mauritania was first peopled by Negroes and by the Sanhadja Berbers. It was the cradle of the Berber Almoravid movement, which in the 11th century laid waste the Ghana empire before conquering Morocco (see *ALMORAVIDS*). The Almoravids imposed Islam upon all the neighbouring peoples. A caravan route at that time linked Mauritania with Morocco. Arab tribes infiltrated by this route, and in the 15th century submerged the Berbers. The nomadic tribes formed several powerful confederations: Trarza and Brakna, who dominated the Senegal river; Kunta in the east; and Regeibat in the north.

In 1442 Portuguese vessels rounded Cape Blanc, and in 1448 the Portuguese founded the fort of Arguin, from whence they derived gold, gum arabic and slaves. Later the French and English frequented Portendick, and then the French settled at St. Louis at the mouth of the Senegal river. In 1858 Col. L. L. C. Faidherbe ended Moorish domination over lower Senegal. After 1898 an Islamic specialist, Xavier Coppolani, succeeded, without a struggle, in rallying all the Moors of the south to France. He was assassinated in 1905 and his work completed by Col. H. J. É. Gouraud, who occupied Tagant in 1907 and Adrar in 1909. The Regeibat were not finally pacified until after World War I.

Mauritania was constituted a territory of French West Africa in 1920 and later became a colony; it was at first governed from St. Louis in Senegal. In 1946 Mauritania became an overseas territory and in 1957, after repulsing an attack by Moroccan irregulars on the north, elected a government under Mokhtarould Daddah, who established the new capital at Nouakchott. In 1958 Mauritania voted to become a member state of the French Community, and on Nov. 28, 1960, its full independence was declared. It became a member of the United Nations in Oct. 1961.

By far the largest political party is the Mauritanian Regroupment party (P.R.M.), formed in 1958 by an amalgamation of the two largest parties. Certain elements, especially in the north, support the persistent claim of Morocco to sovereignty over Mauritania. Relations with Morocco have constituted the country's most serious problem in foreign relations. Moroccan raids were repulsed in 1956 and 1957, and in 1961 Moroccan claims were reasserted by King Hassan II. (Hu. De.)

Population, Administration and Social Conditions, and Economy.—Mauritania is administered by a council of ministers nominated by the premier. The legislative body (*assemblée nationale*) consists of members elected for five-year terms by universal suffrage; it elects the premier. The over-all policy of the country, however, is decided and conducted by the president, who is the head of state.

The country is divided into 11 *cercles*: Baie du Lévrier (chief town Port Étienne), Inchiri (Akjoujt), Trarza (Rosso), Brakna (Aleg), Gorgol (Kaédi), Guidimaka (Sélibaby), Assaba (Kiffa), Tagant (Tidjikdja), Hodh west (Aioun el Atrouss), Hodh east (Néma) and Adrar (Atar). The largest town is Kaédi (pop. [1962 est.] 9,123); the second, Atar (pop. [1962 est.] 7,220).

Though Islam is the state religion, the constitution guarantees religious freedom. Mauritania, especially the ancient city of Chinguetti, was for centuries a centre of Islamic culture and learning, famous throughout the Muslim world.

Educational development has been slow mainly because of limited public funds and the problem of nomad children. By the early 1960s, however, there were more than 150 primary schools, 50 secondary schools and about 90 schools for nomad children.

Cattle—Zebu (Brahman) of the Maure type—have long been the greatest resource of the people of Mauritania. Sheep and goats are raised along the coast, and camels are the beasts of burden all over the country. Agriculture is of minor importance. The trade in gum arabic, traditionally of great importance as an export

product, declined in the 20th century. A few of the Moors are fishermen, but Port Étienne has become a fishing centre for men from the Canary Islands and a crayfish-catching centre for Bretons. Canning factories have been built, and fish and preserved food represent half the total exports in weight and value.

Mauritania is also rich in mineral resources: iron from the region of Fort Gouraud, where the deposits are conservatively estimated at 100,000,000 tons of high-grade ore, and from Gleitat el Kader; and copper from Akjoujit. Two companies, of which the one concerned with iron is an international consortium, have supplied equipment to mine the deposits. The iron will be taken by a projected railway to Port Étienne. In this way the country is becoming provided with lines of communication, supplementing the trans-Sahara road from Rosso, in southwest Mauritania, to Morocco, by way of Nouakchott, Akjoujit, Atar, Fort Gouraud and Fort Trinquet. The country has no class A airports but several of class B. The government-controlled Radio Mauritanie in Nouakchott broadcasts in French and Arabic. Mauritania became a member of the West African Monetary union (established May 1962) and thus remained in the franc area.

See also FRENCH WEST AFRICA; SAHARA; SENEGAL, REPUBLIC OF.

See Molchatar ould Hamidoun, *Précis sur la Mauritanie* (1952); Pierre Munier, *L'Assaba* (1952). Current history and statistics are summarized annually in *Britannica Book of the Year*.

MAURITIUS, an island and British colony in the Indian Ocean, lies about 500 mi. (800 km.) E of the Malagasy Republic, between longitude 57° 17' and 57° 46' E, and latitude 19° 58' and 20° 32' S. The island is pear-shaped, about 38 mi. (61 km.) long and 29 mi. (47 km.) broad, with an area of 720 sq.mi. (1,865 sq.km.). Administered as dependencies of Mauritius are a few small island groups scattered throughout the Indian Ocean, the furthest lying more than 600 mi. (965 km.) to the north. These are Rodrigues (*q.v.*), Agalega (27 sq.mi. [70 sq.km.]), and Carriacou shoals. The dependencies cover approximately 70 sq.mi. (181 sq.km.).

Physical Geography.—Mauritius is wholly volcanic, built up during three periods of volcanism. In the Cretaceous or Early Tertiary a vast volcanic dome was formed but the centre of this either foundered or was blown out in a paroxysmal eruption, so that only a series of jagged, toothlike stumps survive around the edges to form the grotesque bordering mountains of the island. In the Late Tertiary there was a second outpouring of lava, followed by a third in the Pleistocene, in which flow after flow of basalt poured out from a series of low craters aligned across the centre of the island from north-northeast to south-southwest. These later lavas formed a vast, gently sloping dome from which protrude the stumps of the older series.

The highest summit, the Piton de la Rivière Noire, in a block of high country in the southwest of the island, reaches only 2,711 ft. (826 m.), but in other parts of the mountain ring there are peaks almost as high. In the jagged chain behind Port Louis are the Pieter Both (2,690 ft. [795 m.]) and Le Pouce (2,661 ft. [811 m.]). The abruptness of the Mauritian mountains, rising above the smooth slopes of the newer lavas, makes them more impressive than their small elevations would suggest.

The surface of the newer lavas is very slightly trenched by erosion; only the Grand River South East, which with a length of 10 mi. (16 km.) is the principal stream, has cut down to form a sizable gorge. Some of the volcanic craters still contain lakes, and the small streams falling over the western escarpment, on the older lavas, have impressive falls. There are some underground streams in lava tunnels. The whole coastline is girt by a coral reef, and there is also raised coral at several points on the coast, up to 40 ft. (12 m.) above sea level. These formations are ascribed to high sea levels in the Pleistocene and are taken to indicate that volcanism ceased about 100,000 years ago.

Climate.—Mauritius is swept by the southeast trade winds from April to October, and during these months the climate is mild, even chilly on the high ground. From November to March the weather is oppressively hot and humid except at high altitudes, and during this part of the year the island is sometimes visited by

cyclones. Rainfall is heaviest on the southeast-facing slope, rising steadily from about 60 in. (1,525 mm.) annually on the coast to more than 200 in. (5,080 mm.) on the high ground. The west coast is relatively dry, with less than 40 in. (1,015 mm.) in Port Louis. Rain is heaviest in summer but there is no dry season except on the northwestern and western lowlands.

Vegetation.—The vegetation of Mauritius consists predominantly of species introduced since the colonization of the island. Prior to the 17th century the vegetation seems to have been characterized by a wide extent of dense rain forest containing many valuable hardwood timbers; these were extensively exploited in the first two centuries of settlement. Heath and a mossy forest mantled the highest parts, and on the drier lowlands the vegetation was probably a palm savanna. By the middle of the 20th century little was left of these associated groups: about two-fifths of the surface is covered by sugarcane and the rest is occupied largely by heath on the uplands, *Ravenala* thicket (chiefly the traveler's tree) or pine plantations in the other superhumid areas, and grassland with acacias or aloes (*Furcraea*) in the subhumid areas. The ebony forests and the palm savanna are extinct, but endemic species of screwpine (*Pandanus*) are still numerous, and their leaves are used for a variety of purposes, such as making bags.

The Royal Botanical Gardens at Pamplemousses, in the north of the island, were established in 1770 to facilitate the introduction of a wide variety of tropical crops, mainly from Asia. They played an important part in the history not only of Mauritius but also of other lands, notably by providing Zanzibar with cloves in the early 19th century.

Animal Life.—Mauritius has always been an oceanic island, never linked to any land mass. The indigenous fauna was therefore limited and also highly endemic. Two species of bats were the only mammals, and reptiles were limited to two kinds of snakes, confined to an off-lying islet. Birds were more numerous and were distinguished by a large, flightless species, of which the most famous is the dodo (*Raphus cucullatus*). Man and the introduced wild pig had hunted down the last dodo by 1681, and ten other endemic forms are extinct. Rats, like the pigs, were introduced early, and sambur deer were brought by the Dutch. Mongooses were introduced in the 19th century to combat rats, but themselves became a pest. Other mammals include a small hare, a shrewmouse, and the tenrec from the Malagasy Republic. The most significant insect introductions were the common fly and several mosquito species, including the African mosquitoes *Anopheles*

MILES FROM BLACK STAR

JAGGED VOLCANIC MOUNTAINS ON THE PLAINS OF MAURITIUS. SUGARCANE IS GROWING IN THE FOREGROUND

funestus and *Anopheles gambiae*. *Anopheles funestus*, which spread malaria after its introduction about 1865, was finally eradicated by spraying in the 1950s. (HA. C. Bd.)

The People.—The people of Mauritius are all immigrants or descendants of immigrants. About two-thirds are of Indian origin deriving from either northern or southern India, the majority having come from areas around Bihar; about one-quarter are Creoles of mixed African and European, or Indian and European, descent; about 3% are Chinese born in or deriving from southern China; and 2% are Europeans, mostly of French descent. Creole, a French patois, is the lingua franca of the island, although five Indian languages, two Chinese dialects, French, and English are also spoken. The Indians practise several forms of Hinduism. Ceremonies such as firewalking and the sacrifice of animals are performed. Caste has largely disappeared except in marriage, where caste endogamy still is practised. About one-quarter of the Indians are orthodox Sunni Muslims. The Creoles and Europeans are overwhelmingly Roman Catholic. Very few traces of African culture remain among Creoles. About half the Chinese are Roman Catholic; the rest practise traditional forms of Chinese religion. (Bu. B.)

Population.—The population of Mauritius in 1965 numbered 733,000 (not including about 20,000 inhabitants of the dependencies). It was increasing rapidly, following the virtual elimination of malaria in the late 1940s. The rate of increase, about 3% a year, was causing alarm in view of the size of the island. Population density was more than 1,000 to the square mile (one of the highest in the world), and in some rural areas of the northeastern plain densities had risen to more than 1,500 to the square mile. The chief towns (pop. 1962) are Port Louis (89,096), Curepipe (35,275), Beau Bassin-Rose Hill (37,797), and Quatre Bornes (28,389). (HA. C. Bd.)

History.—Mauritius was probably visited by both Arab sailors and Malays during the Middle Ages, and on maps of about 1500 it is shown with an Arabic name. The first European to discover it is believed to have been Domingo Fernandez, and on many 16th-century maps the island appears with the Portuguese name of Cerné. The Portuguese made no settlement on the island, and in 1598 the Dutch took possession and called it "Mauritius" after their stadholder, Maurice of Nassau. The Dutch settlers never numbered more than a few hundred, and the island was abandoned in 1710. The Dutch exploited the island's ebony forests and introduced sugarcane, cotton, domestic animals, and deer.

The French claimed the island in 1715 and called it the Île de France. Until 1767, when the French government assumed direct control, it was governed by the French East India Company. Mahé de La Bourdonnais (see LA BOURDONNAIS, BERTRAND FRANÇOIS MAHÉ, Comte de) did more than any other governor to change what was a small outpost into a prosperous and strong colony. He made sugar planting the main industry and virtually created a Mauritian nationality. The regime introduced in 1767 divided the administration between a governor, primarily charged with military matters, and an intendant. The colony continued to rise in value during the time it was held by the French crown, and to one of the intendants, Pierre Poivre, was due the introduction of the clove, nutmeg, and other spices.

During the long war between France and England, at the beginning of the 19th century, Mauritius was a continual source of harm to English Indiamen and other merchant vessels; and at length the British government determined upon an expedition for its capture. This was effected in 1810, and upon the restoration of peace in 1814 the possession of the island was confirmed to Britain by the Treaty of Paris. By the eighth article of capitulation the inhabitants retain their own laws, customs, and religion; and thus the island is still partly French in language, habits, and predilections; but its name was changed to that given by the Dutch.

A council of government was first constituted in 1825, consisting of the governor and four officials, but a year later the constitution was amended and a council including unofficial members was introduced. At the emancipation of the slaves (1833), Indian labourers were brought in to work in the fields, and the planters received £2,000,000 compensation for the loss of their slave labour. In

spite of many calamities the island continued to prosper as an important sugar-producing country. Cholera caused the death of 17,000 persons in 1854, and 30,000 died of malaria in 1866–67. In 1892 a cyclone of terrific violence caused 1,200 deaths and immense destruction of property. In 1893 a great part of Port Louis was destroyed by fire. The epidemic of surra in 1902 killed all the draft oxen and necessitated the introduction of mechanical transport. In 1911 the *Phytalus smithi* beetle was found to be attacking the sugarcane.

Prosperity resulting from the high price of sugar in World War I made possible many improvement plans, but the price fell once more, and at the end of 1930 the condition of the sugar industry was extremely serious. A cyclone in 1931 and a severe drought in 1934 accentuated the difficulties of the planters, but with substantial sugar crops the position subsequently improved. Because imports were restricted during World War II, tens of thousands of acres formerly under sugarcane were planted with maize (corn), manioc, and sweet potatoes, and for a time Mauritius became entirely independent of imports of rice, the staple food of the people. In 1945 an intense cyclone wreaked enormous damage. After the war the island's prosperity increased, and in 1957 a five-year development program was inaugurated, with the purpose of raising agricultural and industrial productivity, extending the scope of the social services, and overcoming the employment problems created by the rapid increase of population. Early in 1960 Mauritius was struck by severe cyclones causing many casualties and destroying a large part of the sugar crop, but the economic consequences were mitigated by grants and loans from the British government.

In 1947 the colony was granted a broader political franchise, the number of registered electors rising from 12,000 to 71,723, and a ministerial form of government was introduced in 1957. Universal adult suffrage in 1958 increased the electorate to 210,000. In 1961, following a constitutional conference in London, the leader of the majority Mauritius Labour Party became chief minister.

A further constitutional conference in 1965 made provision for the attainment of full internal self-government after a general election in 1966 and independence six months later. The entrenched provisions of the independence constitution would include the appointment of an ombudsman. (W. H. Is.)

Administration and Social Conditions.—Mauritius made rapid constitutional progress after World War II, and in 1964 a new constitution gave the colony a considerable measure of self-government. A majority of the Legislative Assembly is elected by universal adult franchise. In practice there is also a majority of elected members on the Executive Council, and there is also a Council of Ministers. The governor retains only limited powers, principally the right to nominate members to represent minorities in the Legislative Assembly. The chief minister and most of the other ministers belong to the majority party, the multiracial Labour Party, but in 1964 an all-party government was formed, with only the governor and chief secretary as official members of the party.

Port Louis (*q.v.*), the capital, is administered by a municipal corporation; the first mayor was appointed in 1854. The other principal towns have two councils. The island is divided into nine districts, which have endured since the 18th century, although their boundaries were finally defined only in 1871. Except as registration and judicial areas, they no longer have any administrative function.

Living Conditions.—Most Mauritians are poor, and about 250,000 are directly dependent on the sugar industry. Some of these still live on estate camps, but most live in villages of Indian-type mud-and-thatch houses. In the urban areas, especially in Port Louis, overcrowding is intense, and there is an average of three persons to a room over the whole island. Parts of Port Louis have about 1,000 persons to the acre. In the mid-1960s there was comparatively little unemployment, but there was considerable underemployment, and the rapid increase in population was not being balanced by an increase in employment opportunities.

Welfare Services.—A social welfare department, created after

World War II, established village welfare centres in all parts of the island, and these provide some basic medical services. Besides several general hospitals there are a number of sugar-estate hospitals. Health is generally poor: with the elimination of malaria the main causes of sickness are enteric diseases and hookworm, which affects at least nine-tenths of the population. Nutrition is widely inadequate. However, great improvements were made after World War II, especially in infant mortality. The death rate fell from 36 to 8.6 per 1,000 between 1945 and 1964. Piped water has been extended to all parts of the island. There is a noncontributory old-age pension scheme.

Justice.—Mauritius has largely retained the old French laws, as stipulated in the terms of surrender in 1810, except insofar as these have been modified by colonial ordinances. A Supreme Court of Civil and Criminal Justice was established in 1831; it is also a Court of Admiralty, and it decides appeals from the Supreme Court of the Seychelles. A Court of Criminal Appeal was set up in 1955 to hear appeals from the Supreme Court.

Education.—In the mid-1960s about 550 primary schools, of which about 210 were government institutions, were attended by about three-quarters of the children of primary-school age, education not being compulsory. There were about 70 secondary schools, but almost all of these were private institutions, often of doubtful standing. An agricultural college is the only post-secondary institution, although some higher as well as secondary education is provided at the Royal College at Curepipe, the principal boys' institution. In 1965 a university college was established. More than 1,000 Mauritian students were receiving higher education overseas in the mid-1960s.

Defense.—The Royal Pioneer Corps (Mauritius) is recruited locally, and a small Mauritius Naval Volunteer Force was created in 1949. In 1960 the British garrison was withdrawn from the island after an occupation that had lasted 150 years.

The Economy.—Mauritius is almost entirely dependent on the cultivation of sugarcane, the crop occupying two-fifths of the whole island and more than four-fifths of the arable land. There is no crop rotation, and milk, coconut oil, and vegetables are almost the only foodstuffs produced locally. Fishing is practised, and the entire annual catch of about 2,000 tons is consumed locally. A beginning has been made in the farming of fresh-water fish.

The sugar industry comprises about 30 large estates, of which most have factories, together with about 13,000 small planters, who cultivate areas ranging from more than 100 ac. (40 ha.) to as little as a single row of canes, and about 3,000 *métayers*, frequently part-time estate labourers who cultivate some of the land of the larger estates on a sharecropping basis. There are great variations in yield, the large estates being much the most efficient producers. Cane is grown in all parts of the island except the mountains, the superhumid uplands and some subhumid areas in the west; although the development of new cane varieties led to considerable extension of the area after World War II. Production exceeds 600,000 tons of sugar in good years. This is larger than the quotas in the world and Commonwealth sugar agreements, but underproduction elsewhere makes it possible to market the surplus. Most of the output goes to the United Kingdom and Canada.

The only other important primary industry is the production of tea on a small area of the superhumid central uplands. By the mid-1960s the tea acreage planted was still less than 4,000 ac. (1,620 ha.) though it was estimated that from 15,000 to 30,000 ac. (6,000 to 12,000 ha.) were suitable for the crop. By the mid-1960s production exceeded local consumption, although the home market remained more remunerative than export. A small aloefibre industry, concentrated in the subhumid west, is in decline, and tobacco of a relatively low grade is produced for the local market. Market gardening and the raising of mainly stall-fed cattle complete the list of primary industries. Copra is exported from the dependencies.

The sugar and tea factories, together with a government sack factory, a cigarette factory, and a match factory, are the only significant secondary industries. Power for the sugar mills is supplied by burning the crushed residue of sugarcane, and for other industries by electricity generated from hydroelectric plants in the

southwest and a diesel plant at Port Louis.

Trade and Finance.—Both imports and exports approached Rs. 400,000,000 annually in the mid-1960s. Almost the whole value of exports is accounted for by sugar, molasses, and rum. Most foodstuffs and manufactures are imported: rice, the staple food, comes from Burma under a long-term agreement signed in 1954.

Banking facilities are provided by the Mauritius Commercial Bank, the Mercantile Bank of India, and Barclays' Bank (Dominion, Colonial, and Overseas). The Mauritius Agricultural Bank was founded in 1936, the capital being provided by the government. The local currency is the Mauritius rupee, equivalent to 1s. 6d. sterling, divided into 100 cents. A new note issue was established in 1954. Revenue is almost wholly locally derived; income tax was introduced in 1950.

Communications.—Mauritius has about 820 mi. (1,320 km.) of public roads, of which about two-thirds are bitumen. Bus routes serve every town and village in the island. The standard-gauge railway system, covering less than 100 mi. (160 km.), catered only to freight traffic and was scrapped in 1965. Port Louis is the only seaport, handling nearly 2,000,000 tons of shipping a year; most of the merchandise is handled by lighters. Regular cargo services are maintained with the United Kingdom, France, the Republic of South Africa, and Japan, and regular passenger services with South Africa, but passenger services direct to the United Kingdom are infrequent. The airport at Plaisance is an important stop on the South Africa–Australia routes of certain airlines, and there is a weekly service to London and a thrice-weekly service to France via the Malagasy Republic. The government runs the Mauritius Broadcasting Service.

MAUROIS, ANDRÉ, the name, originally a pseudonym, adopted by ÉMILE HERZOG (1885–), French man of letters, novelist, essayist and (pre-eminently) biographer, who was born at Elbeuf, Normandy, on July 26, 1885, the son of a textile manufacturer originally of Alsace. He was educated at Rouen, where he came under the formative influence of the philosopher Alain (*q.v.*), of whom in later life he published a biography (*Alain*, 1949). A liaison officer with the British army in World War I, it was as an affectionate interpreter of the English to the French—and to themselves—in *Les Silences du Colonel Bramble* (1918) and *Les Discours du Docteur O'Grady* (1922) that Maurois won his first popularity. This was consolidated by a series of short, romanticized biographies of English figures: Shelley, Disraeli, Byron, Cecil Rhodes, Edward VII and others. After World War II, which he spent in the United States and with the Allied forces in north Africa, appeared his most solid biographical studies: the lives of George Sand (*Lélia*, 1952), Hugo (*Olympio*, 1954) and *Les Trois Dumas* (1957). His extensive production includes popular histories of England, the United States and France, and critical studies of which the most important is his profound *À la recherche de Marcel Proust* (1949). In 1938 he was elected to the Académie Française and was made a knight of the British empire.

See M. Droit, *André Maurois* (1953).

(H. G. WH.)

MAUROPUS, JOHN (fl. 11th century A.D.), archbishop of Euchaita in Asia Minor, Byzantine scholar and ecclesiastic, left a number of works, mainly sermons, poems in classical metre, letters, a saint's life, and a large collection of canons or church hymns (many unpublished). The chronology of Mauropus' life is uncertain. It is however clear that he was a private tutor in Constantinople in the first quarter of the 11th century, and then came to court in Constantine IX's reign (1042–55) at the instance of his friend and pupil Michael Psellus (*q.v.*), and lectured in the re-

organized university. At some time he became a monk and archbishop of Euchaita.

MAURRAS, CHARLES (1868-1952), French writer and political theorist, one of the major intellectual influences in Europe during the first half of the 20th century, was born at Martigues, Provence, on April 20, 1868, of a royalist and Catholic family. During his studies in the Collège de Sacré-Coeur at Aix-en-Provence an illness, in 1881, made him permanently stone-deaf, and he took refuge in books. Having lost the faith of his parents, he built up for himself a lucid conception of the world, aided by the great poets, from Homer to Mistral, as well as the Greek and Roman philosophers. In 1891, soon after his arrival in Paris, he founded, with Jean Moréas, a group of young poets in opposition to the Symbolists later known as the *école romane*. During the same years, he elaborated a complete system of political philosophy, based on the notions of Greek harmony, Roman order and modern positivism. After the Dreyfus affair, in June 1899, he was one of the founders of *L'Action française*, a review devoted to "integral nationalism," which was to become, in 1908, with help of Léon Daudet, a daily paper, the organ of the royalist party. It exercised a considerable influence, because of its incessant propaganda as well as the credit Maurras had acquired as the author of *Le Chemin de paradis* (1895), *Anthinéa* (1901) and *Les Amants de Venise* (1902), and of *L'Enquête sur la monarchie* (1900) and *L'Avenir de l'intelligence* (1905). After World War I, he was still admired in literary quarters as the poet of *La Musique intérieure* (1925), the critic of *Barbarie et poésie* (1925) and the memorialist of *Au signe de Flore* (1931). But he lost some of his political influence when on Dec. 29, 1926, the Holy See placed some of his books and *L'Action française* on the Index, thus depriving him of many sympathizers among the French clergy.

Maurras was received into the Académie Française in 1939. When World War II broke out he had long been a friend of the Italian fascists who, in fact, owed much to his doctrines. During the German occupation he became a strong supporter of the Pétain government. Arrested in Sept. 1944, he was, in Jan. 1945, sentenced to life imprisonment and excluded from the Académie. In 1952 he was released on grounds of health from the prison at Clairvaux and entered the St. Symphorien clinic in Tours. Reconciled with the Church, he produced the poems of *La Balance intérieure* (1952) and a book on *Le Bienheureux Pie X, sauveur de la France* (1953) before he died in St. Symphorien on Nov. 16, 1952.

MAURY, JEAN SIFFREIN (1746-1817), French cardinal who, as the abbé Maury, was an outspoken opponent of the Revolution but later transferred his allegiance to Napoleon, was born at Valréas in the Comtat-Venaissin on June 26, 1746, the son of a cobbler. Educated at the seminary in Avignon, he took holy orders and began to make his reputation, from 1771, with *éloges* or panegyrics of saints and churchmen. He thus won appointments to preach before Louis XVI of France, who remarked on one of his sermons: "If the abbé had only said a few words on religion, he would have touched on every possible subject." Maury's essay on pulpit eloquence ("*Essai sur l'éloquence de la chaire*," first published with other discourses in 1777) remains a classic; and his efforts were rewarded with the priory of Lihons-Santerre in 1781 and with election to the Académie Française in 1785.

Deputy for the clergy of the *bailliage* of Péronne in the estates-general of 1789, Maury presented a list of grievances demanding considerable reforms; but when the Revolution took shape he emerged as a defender of the *ancien régime*. When many of his

friends took refuge abroad, he remained in the Constituent Assembly to resist the alienation of church property and the subordination of the royal power to the idea of popular sovereignty. His witty sayings did much to deflect violent hostility from his person, but he was satirized in scathing pamphlets. After the dissolution of the Constituent Assembly he emigrated.

Called to Rome by Pope Pius VI, Maury was made titular bishop of Nicaea in May 1792 and then was sent as nuncio to the diet of the Holy Roman empire at Frankfurt (June-July). He was created cardinal in Feb. 1794 and made bishop of Montefiascone, but had to seek refuge in Venice with other cardinals after the French occupation of Rome (1798). On his return to Rome in 1800, he was ambassador to the Holy See for the titular Louis XVIII.

When Napoleon had been proclaimed emperor, Maury wrote to congratulate him (Aug. 1804) and at last returned to France (May 1806). In Oct. 1810, however, Napoleon, whom Pius VII had excommunicated in 1809, nominated Maury to the archbishopric of Paris, which Joseph Fesch (q.v.) would not accept. Maury undertook the administration of the diocese of Paris and ignored the captive pope's brief (Nov. 5) ordering him to give it up. On the first Restoration (1814) he left France for Rome and was suspended from his episcopal functions in Montefiascone. Arrested in May 1815 (during the Hundred Days), he was imprisoned for more than three months in the Castel Sant' Angelo. He then resigned Montefiascone and made his peace with the pope. Maury died in Rome on May 11, 1817. A selection of his writings, in five volumes, appeared in 1827 and an edition by A. Ricard of his diplomatic correspondence, with some unpublished writings, in two volumes, in 1891.

MAURY, MATTHEW FONTAINE (1806-1873), U.S. naval officer and hydrographer whose oceanographical research received wide recognition, was born in Spotsylvania county, Va. In 1825 he entered the navy as midshipman, circumnavigating the globe in the "Vincennes" during a cruise of four years (1826-30). In 1839 an accident resulted in permanent lameness and unfitted him for active service, and in 1841 he was placed in charge of the depot of charts and instruments, out of which grew the U.S. naval observatory and the hydrographic office. He laboured to obtain observations as to the winds and currents by distributing to captains of vessels specially prepared logbooks. One result was to show the necessity for combined action on the part of maritime nations in regard to ocean meteorology. This led to an international conference at Brussels in 1853, which produced great benefit to navigation as well as indirect benefit to meteorology.

In 1855 he was given the rank of commander. On the outbreak of the Civil War in 1861, Maury threw in his lot with the South, and became head of coast, harbour and river defenses. He invented an electric torpedo for harbour defense, and in 1862 was ordered to England to purchase torpedo material, etc. After the war he went to Mexico, and as the imperial commissioner of immigration of the emperor Maximilian, attempted to found a Virginian colony there. While there he introduced the cultivation of cinchona. The scheme of colonization was abandoned by the emperor (1866), and Maury settled for a while in England, where he was presented with a testimonial raised by public subscriptions. In 1868 he accepted the professorship of meteorology in the Virginia Military institute, and settled at Lexington, Va., where he died on Feb. 1, 1873.

Among works published by Maury are the papers contributed by him to the *Astronomical Observations* of the U.S. observatory; *Letters on the American and Atlantic Slopes of South America* (1853); *Physical Geography of the Sea* (1855); *Letter Concerning Lanes for Steamers Crossing the Atlantic* (1855); *Physical Geography* (1864); *Manual of Geography* (1871).

MAUSOLEUM: see MONUMENTS AND MEMORIALS.

MAUSOLUS (MAUS[s]OL[L]os), satrap and practically ruler of Caria (377/376–353/352 B.C.). The part he took in the revolt against Artaxerxes II of Persia, his conquest of a great part of Lycia, Ionia and of several of the Greek islands, his co-operation with the Rhodians and their allies in the war against Athens (357–355), and the removal of his capital from Mylasa, the ancient seat of the Carian dynasts, to Halicarnassus are the leading facts of his history. Mausolus is best known from the tomb (the Mausoleum) erected for him by his sister and widow Artemisia. The architects Satyrus and Pythius and the sculptors Scopas, Leochares, Bryaxis and Timotheus finished the work after her death in 351/350. See HALICARNASSUS.

MAUSS, MARCEL (1872–1950), French sociologist and social anthropologist, was one of the advocates of modern anthropological thought. Born at Épinal, on May 10, 1872, of a Jewish family, Mauss was the nephew of Émile Durkheim, who contributed much to his intellectual formation. Mauss succeeded Durkheim as editor of *L'Année Sociologique* and took an important part in the preparation of his uncle's works, especially *Le Suicide*. In 1902 he became professor of primitive religion at the École Pratique des Hautes Études in Paris and in 1931 was appointed to the Collège de France. By the side of Jean Jaurès, he had been active in his youth in the French socialist movement. He was one of the founders of the Institut d'Ethnologie of the University of Paris in 1925. He died in Paris in Feb. 1950.

Although he never did field work, Mauss turned the attention of a generation of French sociologists, philosophers and psychologists toward ethnographical studies. He published very little, but had an amazing knowledge of anthropological literature and a flair for new and promising trends. Rather than explaining native customs after preconceived ideas, Mauss took pains to distinguish native points of view and to preserve their freshness and specificity. He thus became one of the early advocates of a close relationship between psychology and anthropology. Mauss was the exponent of the principle of reciprocity; i.e., the conception of social life as a network of obligations expressed in the exchange of goods. His outstanding work was *Essai sur le Don* (1898; Eng. trans., *The Gift: Forms and Functions of Exchange in Archaic Societies*, 1954). This and other articles are collected in book form: *Sociologie et Anthropologie* (1950). (C. LE.-S.)

MAUVE, ANTON (1838–1888), Dutch painter, who, like his friends Jozef Israëls and the three Maris brothers, was profoundly influenced by J. B. C. Corot, J. F. Millet and the Barbizon painters, and whose work consists largely of landscapes and scenes of rural life. He was born at Zaandam, near Amsterdam, on Sept. 18, 1838, and settled at The Hague in 1870, painting in the neighbouring fishing village of Scheveningen. In 1885 he went to live in the country at Laren, near Hilversum, and died at Arnhem on Feb. 5, 1888. Mauve's pictures are subdued in colour, and close to Corot in their harmonies of grays and blues. He was an accomplished water-colourist. His wife, Jet Cabentus, was a cousin of Vincent van Gogh, whom Mauve was able to help with advice about oil painting in 1881 and 1882. (A. Bs.)

MAVROKORDATOS (MAVROKORDATO), the name of a family of Phanariot Greeks, of whom the best known are the following:

ALEXANDROS MAVROKORDATOS THE EXAPORITE (1641–1709), born in Constantinople, Nov. 7, 1641, the son of a merchant of Chios, studied at Rome, Padua and Bologna and became physician and then dragoman (1673) to the sultan. Appointed minister plenipotentiary, he negotiated the treaty of Karlowitz (1699). His influence at the Porte was considerable and he ameliorated the conditions of the sultan's Christian subjects. He died in Constantinople, Dec. 23, 1709.

NIKOLAOS MAVROKORDATOS (1680–1730), son of Alexandros, was born in Constantinople on May 3, 1680, a scholar and linguist who succeeded his father as first dragoman in 1698. In the years 1709–10 and 1711–16 he was hospodar (prince) of Moldavia. Appointed hospodar of Walachia (1716) he was taken prisoner by the Austrians but set free and restored in 1719. The first Greek ruler in the Danubian principalities, he introduced there Greek manners, language and costume, a splendid court and administration by Greek officials who were detested by the Rumanians. He en-

couraged learning and founded libraries.

PRINCE ALEXANDROS MAVROKORDATOS (1791–1865), Greek statesman and great-great grandson of his namesake, was born in Constantinople on Feb. 11, 1791. In 1812 he went to the court of his uncle, Ioannis Karadja, hospodar of Walachia with whom he passed into exile in Russia and Italy (1817). In Aug. 1821, shortly after the outbreak of the Greek War of Independence, he joined a Greek camp near Tripolitsa in the Morea. Disgusted with the aims of the leading Moreots and finding that his political wisdom was not wanted, he moved in September to Missolonghi in western Greece, where he set up an administration. In Jan. 1822 he presided over the first Greek national assembly at Epidaurus and took a leading part in drawing up a constitution. He had no illusions however about the central institutions it established and, though elected president of the executive, he soon returned to his command at Missolonghi. He failed to thrust into Epirus and join the Souliots; his troops (he was not present) were defeated at Peta on July 16, but he held out at Missolonghi. In 1823 he returned to the central government and along with Georgios Kountouriotis, the new president of the executive, faced the opposition of Theodoros Kolokotronis (q.v.) and others. When in 1825 Ibrahim Pasha threatened the Morea, he led forces against the Egyptians and barely escaped capture when the island of Sfaktiria was taken. Upon his return to the seat of government, he was much concerned with foreign policy. Although often regarded as pro-English, he had no desire to rely exclusively on Great Britain, but wished to enlist the support of all the powers, Austria included, and to stimulate rivalry between them. He therefore did not approve, though he was powerless to avert, the Greek demand for British protection (June–July 1825). Under the regime of Count I. A. Kapodistrias, who ignored him, he joined the so-called constitutional opposition. Under King Otho he became minister of finance and in 1833 prime minister. From 1834 onward he was Greek envoy in Munich, Berlin, London and—after a short period as prime minister in 1841—in Constantinople. After the revolution of 1843 he was again prime minister in 1844 and in 1854–55. He died on the island of Aegina on Aug. 18, 1865.

See A. A. C. Stourdza, *L'Europe orientale et le rôle historique des Maurocordato 1660–1830* (1913). (D. Dn.)

MAWER, SIR ALLEN (1879–1942), English philologist and student of place names, was born in Bow, London, on May 8, 1879.

A graduate of Cambridge university, Mawer taught at several provincial universities before coming to London, where he was provost of University college from 1930 until his death. His first interest was in early English and Scandinavian history and literature (*The Vikings*, 1913), but from 1920 all his work was in the field of English toponymy. He was one of the founders of the English Place-Name society (1924), director of its Survey of English Place Names until his death, and joint author of 14 of the 17 county surveys published by 1942, as well as of several studies concerned with English place-name research. He was knighted in 1937. Mawer died on July 22, 1942, at Broxbourne, Hertfordshire. (M. S. Br.)

MAWLAIK, the administrative centre of the Upper Chindwin district of the Union of Burma. Pop. (1953) 3,042. The town was a creation of the British period and is pleasantly situated on low cliffs on the western bank of the Chindwin. An earlier centre, Kindat, a few miles farther up the river on the east bank, was abandoned as it was found to be unhealthy; indeed much of the Upper Chindwin district had a bad reputation for fever. The district consists of forested hills, the few settlements being mainly along the river. Homalin, 100 mi. N.N.E. of Mawlaik, is the normal high-water limit of navigation by steamers and launches; Pantha (about 12 mi. E. of which is the small oilfield of Indaw) is the limit of low-water navigation. The port of Kalewa to the south, where the Myittha enters the Chindwin from the west, became famous during World War II as the point where the Chindwin was crossed by the main Allied army, having made the extremely difficult mountain crossing from India, to drive out the Japanese forces. (L. D. S.)

MAX, ADOLPHE (1869–1939), Belgian Liberal political

leader who as burgomaster of Brussels achieved world-wide fame in World War I for his defiance of the Germans, was born in Brussels on Dec. 30, 1869. He studied at Brussels university, obtaining his law degrees in 1889. From 1896 he was successively provincial councillor of Brabant, councillor of the commune and alderman of Brussels and finally burgomaster (Nov. 1909). In Aug. 1914, when the German troops entered Brussels, he refused to perform his duties under the authority of the German governor and demanded complete freedom of action. He strove with indomitable energy for the rights of the Belgian people and for the reduction of the heavy taxes and requisitions imposed on the town. He also founded a national committee to deal with supplies. The Germans soon took exception to his resistance, and arrested him on Sept. 26, 1914. Imprisoned in the fortress of Namur, he was later sent into Germany. On Nov. 13, 1918, he returned to Belgium where he was welcomed with enthusiasm. Appointed minister of state on Nov. 21, 1918, he was elected to the chamber of representatives on Nov. 16, 1919. On Feb. 6, 1919, he had been elected to the Belgian academy. Max remained burgomaster till his death in Brussels on Nov. 6, 1939.

See A. Vierset, *Adolphe Max* (1923); O. E. Millard, *Burgomaster Max* (1936).

MAXENTIUS, MARCUS AURELIUS VALERIUS (d. 312), Roman emperor from A.D. 306 to 312, was the son of Maximian (q.v.). On his father's abdication on May 1, 305, he was passed over in favour of Severus, who was made the new *Caesar*, and on Constantius' death in 306 *Augustus*. Severus' moves to disband the praetorian guards and impose the poll tax on the citizens of Rome provoked discontent: Maxentius was proclaimed *Augustus* at Rome on Oct. 28, 306, and recalled his father to the throne. Severus was defeated and killed, and Galerius when he invaded Italy was forced to withdraw. Shortly afterward Maxentius quarreled with his father, who sought refuge with Constantine. Maxentius at first controlled Italy, Spain and Africa, but in 308 the vicar of Africa, L. Domitius Alexander, revolted and proclaimed himself *Augustus*, and in 310 Constantine annexed Spain. Maxentius recovered Africa in 311, but in 312 Constantine invaded Italy and Maxentius was defeated and killed at the battle of the Milvian bridge. Maxentius is represented as a brutal tyrant in our sources, which reflect the propaganda of Constantine, despite the fact that he dropped the persecution of the Christians. He built a huge basilica, which Constantine renamed after himself, and a temple to his son, Romulus, who died before him, in the Roman forum. (A. H. M. J.)

MAXIM, HUDSON (1853–1927), U.S. inventor who developed explosives that were used extensively in World War I, was born at Orneville, Me., on Feb. 3, 1853. He completed his academic studies at Kent's Hill, Me. Though he had little education, his interest in chemistry led him to wide reading and experimentation in the subject. In 1875 he formulated a hypothesis (published in *Scientific American Supplement*, 1889) of the compound nature of atoms not unlike the atomic theory that was later to be generally accepted by scientists.

In 1888 he began to experiment with explosives and in 1890 built a dynamite and powder factory at Maxim, N.J. There, together with R. C. Schupphaus, he developed the Maxim-Schupphaus smokeless powder, the first made in the United States and the first to be adopted by the U.S. government. He next invented a smokeless cannon powder, the cylindrical grains so perforated that it burned with a more rapid combustion, which was used in enormous quantities during World War I. In 1897 he sold his factory and powder inventions to E. I. du Pont de Nemours and company, but remained with the company as a consulting engineer.

He invented "maximite," a high explosive bursting powder which, when placed in torpedoes, resisted the shock of firing and the still greater shock of piercing armour plate without bursting. This powder was then set off by a delayed-action detonating fuse, which was also Maxim's invention. Later he perfected a new smokeless powder, called "stabilite" because of its high stability. "Motorite," a self-combustive substance used to propel torpedoes, was also his invention.

During World War I, Maxim served as chairman of the committee on ordnance and explosives of the naval consulting board. Several of his own inventions at this time were donated to the government. He died on May 6, 1927.

SIR HIRAM STEVENS MAXIM (1840–1916), his brother, was the inventor of the Maxim automatic gun.

MAXIMA AND MINIMA: see CRITICAL POINTS.

MAXIMIAN (MARCUS AURELIUS VALERIUS MAXIMIANUS) (d. 310), Roman emperor from A.D. 286 to 305, was born of humble parentage near Sirmium in Pannonia. He served in the army and was in 285 made *Caesar* by his friend Diocletian, and in the following year (April 1, 286) raised to the rank of *Augustus*. He thus became in theory the junior colleague of Diocletian, but his role was always subordinate. While Diocletian took the surname of *Jovius*, as vicegerent of Jupiter, Maximian was given that of *Herculius*, as his faithful assistant. He was assigned the government of the west, where he subdued the Bagaudae, the rebel peasants of Gaul, but failed to suppress the revolt of Carausius in Britain. On March 1, 293, Constantius Chlorus was appointed his *Caesar* and took over Gaul and recovered Britain. Maximian continued to govern Italy, Spain and Africa, where he subdued the rebel Moorish tribes. On May 1, 305, on the same day that Diocletian abdicated at Nicomedia, he abdicated at Milan, but evidently much against the grain, and retired to a villa in Lucania. When his son Maxentius rebelled in Rome on Oct. 28, 306, he gladly on his invitation resumed the throne, and it was through his prestige with the troops that Severus and Galerius were defeated. Soon afterward he attempted to depose his son, but failed and fled to Constantine, who had recently married his daughter Fausta. In 308 he was invited by Galerius to the conference of Carnuntum and was persuaded by Diocletian to abdicate once more. He returned to Constantine's court, and in 310, taking advantage of his absence on a campaign against the Franks, raised a rebellion at Arles. Constantine promptly marched back and captured him at Marseilles, but spared his life. Shortly afterward he died: he was alleged to have committed suicide in remorse for his rebellion, or, according to a more lurid version, on having been detected by his daughter in an attempt to assassinate Constantine. Maximian is a great persecutor in the Christian tradition, but seems to have done no more than obediently execute in his part of the empire the first edict of Diocletian, which ordered the burning of the Scriptures and the closing of the churches. (A. H. M. J.)

MAXIMILIAN I (1459–1519), Holy Roman emperor from 1493, was born at Wiener Neustadt on March 22, 1459, as an archduke of Austria, being the eldest son of the emperor Frederick III, of the house of Habsburg, by his consort Eleonore (Leonore) of Portugal. After Charles the Bold, duke of Burgundy, had been killed in battle (Jan. 1477), Maximilian was married, by proxy in April and in person in August, to Charles's daughter Mary (q.v.), whose inheritance, both in Burgundy and in the Netherlands, was being invaded by Louis XI of France. Maximilian at once undertook the defense of his wife's dominions; and he defeated the French at Guinegate (Enguinegatte) in Artois on Aug. 7, 1479. He was regarded with suspicion, however, by the estates of Mary's territories in the Netherlands. He suppressed a rising in Gelderland; but his position was weakened by his wife's early death (March 27, 1482). Maximilian claimed to be regent for his son Philip, Mary's heir, but some of the estates refused to recognize his regency. The city of Ghent, having obtained custody of Philip, refused to give him up, and disorder became general. In 1483 Maximilian had to agree to the terms of the treaty of Arras (1482), negotiated by the estates of the Netherlands with Louis XI of France: by this treaty Maximilian's daughter Margaret was betrothed to the dauphin (the future Charles VIII of France) and brought Artois and Franche-Comté to him as her dowry, while the French king's seizure of the duchy of Burgundy and of places in Picardy that Charles the Bold had held was tacitly accepted. Even so, Maximilian continued his struggle in the Netherlands, crushed a rebellion in Utrecht (Sept. 1483) and forced Ghent to deliver Philip into his hands again (July 1485).

Returning to Germany, Maximilian was elected king of the Romans (prospective successor to the emperor) at Frankfurt on

Feb. 16, 1486, and crowned at Aachen on April 9. He then went back to the Netherlands. Allying himself with Francis II of Brittany, he resumed warfare against France. The war, however, was very unpopular with the commercial cities of Flanders; and Maximilian, having entered Bruges in Jan. 1488, was held prisoner there by the citizens from February to May, being released only when his father was approaching with a large force. After a punitive expedition against the Flemings, Maximilian withdrew to Germany late in 1488 and concluded the peace of Frankfurt with the French in July 1489. His deputy in the Netherlands, Albert duke of Saxony, gradually compelled the estates to accept Maximilian as regent. In March 1490 Tirol was added to his possessions when his father's first cousin Sigismund abdicated in his favour. Tirol soon became Maximilian's favourite place of residence.

Francis II of Brittany had died in Sept. 1488, leaving the duchy of Brittany to his heiress, Anne (*q.v.*); and in Dec. 1490 Maximilian was married to Anne by proxy. He was in alliance with England and with Spain for the defense of the duchy, but was himself engaged in fighting for the crown of Hungary, whose king, Matthias Corvinus, had died in April. He drove the Hungarians out of Austria and regained Vienna, where Matthias had ruled since 1485. He could not afford an invasion of Hungary, however, and by the treaty of Pressburg (Bratislava) of Nov. 7, 1491, he recognized Vladislav of Bohemia as king of Hungary, though it was agreed that the succession to both Bohemia and Hungary should pass to the Habsburgs if Vladislav left no male heir. Brittany meanwhile had been overrun by the French, and in Dec. 1491, despite Maximilian's claim, Charles VIII of France married Anne, though Maximilian's daughter Margaret of Austria was kept in France. Maximilian could do nothing against this until, having driven the Turks from Carinthia in 1492, he turned westward to defeat the French at Salins in Franche-Comté (Jan. 1493). Neither the Netherlands nor the German *Reichstag* would support him, however, and in May 1493 he agreed to the peace of Senlis, regaining Artois, Franche-Comté and his daughter Margaret.

On the death of the emperor Frederick III (Aug. 19, 1493) Maximilian became sole ruler over the German kingdom and head of the house of Habsburg; and on March 16, 1494, at Innsbruck, he married Bianca Maria Sforza (d. 1510), sister of the duke of Milan, Gian Galeazzo Sforza. In the Netherlands again later in 1494, he led an expedition against the rebels of Gelderland; made an ineffectual appeal to the Christian sovereigns to help him drive the Turks from Europe; recognized the pretender Perkin Warbeck as the rightful king of England; and formally handed over the government of the Low Countries to his son Philip.

Maximilian's attention was next turned to Italy, where Charles VIII of France was advancing victoriously southward to make himself king of Naples. In March 1495 Maximilian therefore joined Spain, Pope Alexander VI, Milan and Venice in the League of Venice against the French; and at the same time he called the *Reichstag* to Worms, asked it for help in the projected campaign and urged the need to eject the French from Italy. But counter-proposals for the better government of Germany were brought forward, and military help did not materialize. Some reforms were adopted; the public peace was declared permanent (the *Ewige Landfriede*, outlawing private warfare between members of the *Reich*); the imperial chamber (*q.v.*) or *Reichskammergericht* was instituted as a permanent court of justice for the empire, with its seat at Frankfurt; and a tax was voted. These reforms were rendered abortive by the nonpayment of the tax and Maximilian's consequent refusal to work the constitution. Instead, he operated through judicial and financial commissions of his own. He fought another French war and made an ineffectual expedition to Italy, financed by Milan (1496). On the other hand, on Oct. 21, 1496, his son Philip was married to the Spanish infanta Joan, a union destined to produce the vast empire of their son Charles V.

In 1499 the refusal of the Swiss to submit to imperial legal decisions produced a war. Maximilian was forced reluctantly to prepare a punitive expedition. Before he himself could intervene the Swiss had defeated his Swabian and Austrian troops; and the treaty of Basel (Sept. 22, 1499) recognized the Swiss as virtually independent. Maximilian, much chastened by failure, attended

the *Reichstag* of 1500 at Augsburg; asked the assembly to finance the ejection of Louis XII—who had succeeded Charles VIII as king of France in 1498 and had promptly married his widow Anne of Brittany—from the imperial fief of Milan; and accepted the formation of a *Reichsregiment* (supreme council) of 21 electors, princes and others. This would have made him formal president of an oligarchic republic. But the *Regiment* did not work, and it ceased to function after 1502. Maximilian won the support of many younger princes and established his own supreme court. He negotiated with Louis XII and concluded the treaty of Blois (Sept. 22, 1504): his baby grandson Charles was betrothed to Louis XII's baby daughter Claude; Louis kept Milan, doing homage and paying 200,000 ducats; and if Louis had no son, Charles and Claude should succeed to Milan, Blois and Brittany.

A succession dispute over the Wittelsbach duchy of Bavaria-Landshut in 1504 enabled Maximilian to judge the case and propose partition (*see* BAVARIA). Rupert of the Palatinate, a disappointed litigant, attempted violence. Maximilian raised an imperial force and quickly defeated the rebel. At the *Reichstag* of Cologne (1505) he awarded most of the inheritance to Bavaria-Munich and a lesser share to Rupert's sons, and confiscated several towns and lordships for the house of Habsburg. It was his moment of triumph. The *Reichstag* was tired of constitutional experiments. Committees of princes could not govern. Maximilian could occasionally exercise authority. The Venetian envoys reported home that he was "a true emperor and ruler of Germany."

But foreign affairs went badly. Louis XII denounced the treaty of Blois; Maximilian's son Philip, king of Castile since his mother-in-law Isabella's death in 1504, died in 1506; and the infant Charles's hope of succession was dubious. However, Maximilian established his daughter Margaret as regent in the Netherlands. If the *Reichstag* of Constance (1507) restored the *Reichskammergericht* in its permanent, if not very effective, form, it also voted a moderate force to accompany Maximilian to Rome for his coronation as emperor. Maximilian started for Rome, but was faced with Venetian resistance; and no imperial troops appeared. At Trent on Feb. 4, 1508, he assumed, with Pope Julius II's consent, the title of "emperor elect." Then, to recover long-lost imperial territory, he began a war against Venice which lasted intermittently for eight years and ultimately ruined him, since the *Reichstag* would vote nothing for a struggle so disastrous for German trade. Negotiations at Cambrai led to a treaty with France against Venice (Dec. 10, 1508); and in 1509 Spain and the pope also joined Maximilian's side (the League of Cambrai); but he had little success.

When Julius made a separate peace with Venice and set himself to drive the French out of Italy (1510), Maximilian joined Louis XII in summoning a general council for church reform at Pisa. Being again a widower, he even considered getting himself elected pope. But eventually he joined the pope's Holy League against France. Having no troops, he attached himself as an adviser to Henry VIII's English army in Artois and was largely responsible for its victory in the battle of the Spurs (Aug. 16, 1513).

Eastern affairs, the danger that Poland, Bohemia and Hungary might unite under the Polish Jagiello dynasty, then preoccupied the emperor. His efforts culminated in an agreement at Vienna (1515) whereby Louis, the young son of Vladislav of Bohemia-Hungary, was betrothed to Maximilian's granddaughter Mary, and her brother Ferdinand was betrothed to Vladislav's daughter Anne. The treaty bore fruit when Louis died in the great Turkish victory at Mohács (1526) and Ferdinand succeeded him.

Meanwhile the new French king Francis I had again conquered Milan, which Louis XII had lost. Maximilian borrowed money, raised a force and actually entered Milan (March 1516). But his money ran out; and his troops mutinied. He hurried home penniless, leaving Milan to Francis I and Verona to Venice. At the *Reichstag* of Augsburg (1518) he failed to secure the election of his grandson Charles, now ruler of Spain, Naples and the Netherlands, as king of the Romans. His strength was failing. He made for his birthplace but died at Wels on Jan. 12, 1519. He was buried at Wiener Neustadt, though his famous tomb is at Innsbruck.

Simple in his habits, conciliatory in his manner and catholic in his tastes, Maximilian enjoyed great popularity and rarely made a personal enemy. He was a skilled knight and a daring huntsman; a military expert, especially on artillery and the organization of the *Landsknechte* (infantry); a man of letters and a patron of learning and the arts. But he left Germany in even worse anarchy than he found it. As German king he is a controversial figure. His critics accuse him of absorption in Habsburg dynastic aggrandizement and indifference to the good government of Germany. It can be replied that in England, France and Spain in Maximilian's time, strong states were being created by kings, not by medieval oligarchies of nobles; that Maximilian constantly exhorted the *Reichstag* and gatherings of princes or towns to unite under their king and to provide the resources for government and defense, especially against France and Islam; and that Germany's hope of unity lay in a Habsburg monarchy free to impose taxation and to keep a standing army and in the increase of the Austrian lands. What is undoubted is that Maximilian could not be patient and realistic, but plunged into adventures for which he could not pay. Yet as ruler of Austria he laid the foundations of unified government over his various provinces, while his matrimonial arrangements produced the vast empire of Charles V and the long-lived unity of Austria-Bohemia-Hungary.

Maximilian was also an author, and his writings show his inordinate vanity. His *Geheimes Jagdbuch* is a treatise instructing his grandsons in the art of hunting. He inspired the production of *The Dangers and Adventures of the Famous Knight Teuerdank*, an allegorical poem describing his adventures on his journey to marry Mary of Burgundy (first printed by Melchior Püntzing at Nürnberg, with woodcuts by Hans Leonhard Schäußelein, 1517). The *Weisskunig*, an unfinished autobiography of "the young white king," was long considered the work of Maximilian's secretary, Marx Treitzsaurwein, but is now believed to be mostly by Maximilian himself (first published at Vienna in 1775). He also wrote *Freydal* (an allegorical account of his tournaments during his wooing of Mary); *Ehrenpforten*, *Triumphwagen* and *Der weisen Könige Stammbaum* (these three on his own history and on that of the house of Habsburg); and works on miscellaneous subjects such as metallurgy, architecture and gardening. These works were all profusely illustrated, some of them by Albrecht Dürer.

There are editions of Maximilian's correspondence with his daughter Margaret for the years 1507-19 by A. G. Le Glay (1839); of some previously unpublished letters of his on the affairs of the Netherlands by L. P. Gachard (1851-52); and of his correspondence with Sigmund Prūschenk by V. von Kraus (1875).

MAXIMILIAN II (1527-1576), Holy Roman emperor from 1564, was born in Vienna on July 31, 1527, the eldest son of the Austrian archduke and future emperor Ferdinand I and Anna, daughter of Vladislav II, king of Bohemia (Ulászló II of Hungary). He gained experience in warfare and government under his uncle the emperor Charles V, to whose daughter Maria he was married in Sept. 1548 (they were to have nine sons and six daughters; see *HABSBURG: Table II*). The Habsburg family became divided over Charles V's plan for his son, the future Philip II of Spain, to succeed as emperor, either after Ferdinand I, who had already been designated Charles's successor, or possibly, as was rumoured, instead of Ferdinand. By a compromise in 1551, Philip was placed in line of succession after Ferdinand, and Maximilian after Philip. In 1553, Philip was excluded from the succession, but Maximilian remained hostile toward the Spanish Habsburgs.

From 1547 onward Maximilian had developed inclinations toward Lutheranism. The nature of his beliefs has long been disputed; they were ambiguous and uncertain, but he was probably

a humanist Christian without loyalties to the dogmas of any confession. He expressed sympathy for Lutheranism until 1562, but thereafter conformed outwardly to Catholicism by declaring his obedience to that faith and by attending Mass. Nevertheless, in his last years and on his deathbed he refused to confess to a Catholic priest or to receive sacraments from one. While hostile to Calvinists, Maximilian believed that Lutherans and Catholics, if they could not be reconciled, should at least tolerate one another. He was to grant freedom of worship to the Protestant nobility of Austria, Bohemia and Hungary because he needed their financial assistance in the Turkish war. Political necessity partly explained his friendliness toward the German Protestant princes. His conformity to Catholicism probably had similar political reasons, arising from his position as emperor and possible heir of the Spanish kingdoms. His father threatened to disinherit him if he abandoned Catholicism. Therefore, though Maximilian had promised the Protestant electors to adopt the Lutheran Augsburg confession if elected, he assured the Catholic electors of his orthodoxy before his election and coronation as king of the Romans, or successor designate to the empire, at Frankfurt on Nov. 24 and 30, 1562. Having already been proclaimed as the future ruler of Bohemia in 1549 and crowned at Prague on Sept. 20, 1562, he was crowned king of Hungary at Pressburg (Bratislava) on Sept. 8, 1563. On July 25, 1564, he succeeded Ferdinand in the empire and in the two duchies of Austria (which he had been governing from 1552), while his brothers inherited the remaining Habsburg duchies.

Maximilian disappointed the Protestant princes at the imperial diet of Augsburg in 1566 by not fulfilling his earlier promise to invest Protestant administrators of bishoprics with their imperial fiefs. He accepted the reforming decrees of the Council of Trent, but his hopes of measures against the Calvinist elector Palatine, Frederick III, were balked by opposition from Lutheran princes. Nevertheless, the diet granted financial aid for the recently renewed war against the Turks in Hungary. Maximilian's large army engaged in one ineffective campaign before peace was concluded in 1568; the emperor continued to pay tribute to the sultan for Hungary. In Austria, he allowed religious liberty to the Lutheran nobles in 1568 and 1571; he commissioned theologians to draft Lutheran ordinances, but also promoted reform of the Catholic Church. Meanwhile he had become reconciled with Philip II of Spain, who married Maximilian's daughter Anna in 1570. However, the emperor's intercession on behalf of the rebellious Protestant Netherlands failed to moderate Philip's harsh measures against them. In 1570, Maximilian proposed to the diet of Speyer a reform of the imperial military organization, based on a memorandum of Lazarus von Schwendi: the emperor and not the princes, as hitherto, would control the army, and his consent would be necessary before foreign powers could recruit soldiers in the empire. These measures were rejected because the estates would not strengthen the emperor's authority and the Protestant princes suspected an attempt to prevent them from assisting co-religionists in France and the Netherlands. Whereas Protestantism had become the faith of the majority in Austria by the end of his reign, Maximilian prevented the proclamation in Bohemia of the confession of faith agreed on by all the reforming movements in 1575, but promised to respect religious liberty.

From 1573 Maximilian sought election as king of Poland for himself or for his son Ernest. Himself elected king of Poland by a minority party in Dec. 1575, he received no assistance from the imperial diet at Regensburg. He died at Regensburg on Oct. 12, 1576, leaving his lands and his imperial title to his eldest surviving son, Rudolf. Maximilian was a collector of books and a patron of artists, architects and scholars, and of the University of Vienna. He preserved the right to worship according to his own beliefs, but succeeded in few of his political aims. There is an edition of his *Familienkorrespondenz* by V. Bibl, two volumes (1916-21).

MAXIMILIAN (FERDINAND MAXIMILIAN JOSEPH) (1832–1867), archduke of Austria and emperor of Mexico, younger brother of Emperor Francis Joseph I, was born in Vienna on July 6, 1832. Of scholarly bent, he received a superior education. After serving as a rear admiral in the Austrian navy, he was appointed at the age of 25 as governor general of the Lombardo-Venetian kingdom. On Oct. 3, 1863, a committee of Mexican conservatives, exiled by Pres. Benito Juárez, came to Maximilian's palace on the Adriatic sea and invited him to become emperor of Mexico. The invitation had been maneuvered by the French emperor Napoleon III, who wanted to collect a debt from Mexico and further his imperialistic ambitions. After deep deliberation, deluded by a false report that the Mexicans had "voted" him a throne, Maximilian accepted the offer, backed by a pledge that the French army, which had conquered much of Mexico, would remain to support him. With his young wife, Carlota, daughter of Belgium's Leopold I, Maximilian sailed for Mexico in May 1864. He went in good faith as a benevolent ruler; he had dabbled in liberalism and had even discussed socialism with the famed Utopian reformer Robert Owen. On June 10, 1864, the royal pair were crowned in the Cathedral of Mexico. At remodeled Chapultepec palace, high above the city, Maximilian established his court. He created a magnificent park and planned a boulevard from the palace hill to Cathedral square.

Maximilian's tall stature and blond hair caused some Indians to believe that he was an incarnation of their fair-skinned, bearded god Quetzalcoatl, a role that Cortés had played to his advantage. Maximilian, in return, soon regarded himself as the Indians' protector. He upheld Juárez' sweeping reform laws: to the indignation of the landed proprietors, he determined to abolish peonage, and he antagonized the Roman Catholic archbishop of Mexico by refusing to restore vast church holdings confiscated by Juárez. He devised schemes for the education of the masses and started a national art gallery. But the Mexican treasury was so bare that he had to use his own inherited income for daily expenses.

By April 1, 1865, the French army had successfully supported Maximilian by driving his enemy Juárez almost into Texas. At this time, however, the Civil War in the United States ended, and the U.S. was able to turn its attention to Mexico. Regarding the presence of the French troops there as a violation of the Monroe Doctrine, U.S. Secretary of State William H. Seward issued an ultimatum demanding their withdrawal. In July 1866 Carlota rushed to Europe to plead with Napoleon not to abandon her husband. Then she sought help from the pope. Realizing that no aid would be forthcoming, she underwent so great a strain that she lost her sanity.

When the French withdrew in March 1867, Juárez and his troops moved back south. Napoleon expected Maximilian to leave Mexico with the French, but the young emperor felt he could not honourably desert "his people." The Mexican conservative leaders made him supreme commander of the imperialistic army. At Querétaro, Maximilian's small force was surrounded, starved and finally betrayed into capitulation on May 15, 1867. When deliberately given an opportunity to escape, Maximilian refused to save himself. He bore his hardships with fortitude. Wasted by fever and dysentery, he was confined in a dank crypt by Juárez and given a criminal's diet of bread and water. Though Garibaldi, Victor Hugo and half the crowned heads of Europe pleaded for his life, Maximilian was court-martialed, tried and condemned to death. His execution took place on the Hill of Bells outside Querétaro on June 19, 1867.

Maximilian was a luckless, idealistic, politically naïve hero of an impossible dream, whose courage at his death turned a tragedy into a tragedy. As a ruler he vacillated and committed political blunders, but as a man, according to his Mexican private

secretary, he "possessed the most noble, loyal and great heart." Maximilian's various writings in German were collected and published. His empress Carlota never fully recovered her sanity. She survived her husband for six decades, dying in a chateau near Brussels in Jan. 1927.

See Egon Caesar, Count Corti, *Maximilian and Charlotte of Mexico* (1928), with an extensive bibliography; Hudson Strode, *Timeless Mexico* (1944).

MAXIMILIAN I JOSEPH (1756–1825), the first Wittelsbach king of Bavaria (from 1806), was born at Mannheim on May 27, 1756, the second son of Prince Frederick Michael of Palatinate-Zweibrücken. From 1775 to the outbreak of the French Revolution he served with the French regiment of Alsace. When he succeeded his brother Charles II Augustus as duke of Zweibrücken (April 1, 1795), the duchy was already occupied by the French, who retained it under the Franco-Austrian peace of Campo Formio in 1797 (see FRENCH REVOLUTIONARY WARS); but on the death of the elector Charles Theodore of the Palatinate and Bavaria (Feb. 16, 1799) he inherited all the other Wittelsbach lands, becoming elector of Bavaria as Maximilian IV Joseph. These lands, however, were ill-administered, were scattered over southern and western Germany and were occupied by the Austrians. Maximilian Joseph and his minister Maximilian von Montgelas (*q.v.*) were to make Bavaria a consolidated modern state.

Though he had hoped, with Prussia's help, to stay neutral, the elector had to take Austria's side against France when war broke out again in 1799. After the peace of Lunéville, however, he made a treaty of his own with France (Aug. 24, 1801): formally renouncing the long-lost lands west of the Rhine, he won assurances of compensation. Under the *Reichsdeputationshauptschluss* of 1803 (see GERMANY: History), he obtained the formerly episcopal lands of Würzburg, Bamberg, Freising, Augsburg and part of Passau, with 15 imperial cities. Meanwhile, with the help of B. E. Derooy and Karl Philipp Wrede, he was building an army, which in 1805 he brought to France's side against Austria. The Austrians had to cede Tirol, Vorarlberg and other territories to Maximilian, who, however, gave Würzburg up. He also received Ansbach for renouncing distant Berg to France. On Jan. 1, 1806, the elector assumed the title of Maximilian I, king of Bavaria.

Obliged to join the Confederation of the Rhine (July 12, 1806), Bavaria took France's side against Prussia in 1806–07 and against Austria again in 1809. So in 1810 Maximilian, for ceding southern Tirol to Napoleonic Italy, received Salzburg, the Innviertel and Regensburg. Though he disliked Napoleon's Austrian marriage (1810), he sent 30,000 men to accompany the disastrous invasion of Russia (1812). On Oct. 7, 1813, however, he accepted the terms procured by Wrede from Austria: for his turning against Napoleon, the integrity of his kingdom was guaranteed (treaty of Ried, Oct. 8). He then exchanged Tirol and Vorarlberg with Austria for Würzburg and Aschaffenburg (1814). Finally he received a collection of Palatinate and other lands west of the Rhine—without, however, any territorial link with Bavaria—for retroceding the Innviertel and most of Salzburg (1816).

Having dismissed Montgelas, the architect of his kingdom, in 1817, Maximilian on May 26, 1818, granted Bavaria a constitution with a bicameral parliament; but the parliament's first session was so stormy that he thought of revoking the constitution (1819). Yet he won his subjects' affection, so that his dynasty could hold together the rather disparate lands that he had united. He died at Nymphenburg on Oct. 13, 1825.

Married in 1785 to Wilhelmine of Hesse-Darmstadt (d. 1796) and in 1796 to Caroline of Baden (1776–1841), Maximilian was survived by 10 of his 13 children, including his successor Louis I (*q.v.*) and daughters married in his lifetime to Eugène de Beauharnais (1806), to Francis I of Austria (1816), to John of Saxony (1822), to Frederick William IV of Prussia (1823) and to the Austrian archduke Francis Charles (1824).

See Prince Adalbert of Bavaria, *Max I. Joseph von Bayern* (1957). (K. O. v. A.)

MAXIMILIAN II (1811–1864), king of Bavaria from 1848, was born in Munich on Nov. 28, 1811, the eldest son of King Louis I and his consort Therese of Saxe-Hildburghausen. He

CULVER PICTURES, INC.
MAXIMILIAN AND CARLOTA

studied history and political science at Göttingen (1829) and at Berlin (1831) and then traveled extensively through Germany, Greece and Italy. As crown prince he surrounded himself with academics and artists, among whom the historian Leopold von Ranke took pride of place. By his marriage (1842) to Princess Marie of Prussia he had two sons, the future kings Louis II and Otto. He succeeded to the throne at his father's abdication on March 21, 1848.

Maximilian wished to make Bavaria the third German force in a triad (*Trias*) with Austria and Prussia, but this brought him into conflict with the German parliament at Frankfurt (see GERMANY: *History*). He had to call on Prussian troops to help him suppress a revolt in the Palatinate (1849), but he refused a closer alliance with Prussia. Ludwig von der Pfordten, who became Bavarian chief minister in April 1849, was in fact inclined rather to take a pro-Austrian attitude. The idea of a "third force" in German affairs was never realized, though Pfordten succeeded in obtaining great influence in the diet of the German confederation by working together with other German states.

Maximilian was more successful in his efforts to make Munich a centre of Germany's intellectual and artistic life. Large-scale research projects were furthered by the establishment of departments of the sciences, technology and history at the Bavarian Academy of Sciences. The king appointed well-known scholars to academic posts in Bavaria and remained in personal contact with them. At times these scholars and artists also meddled in politics, though it is hard to prove the extent of their influence: the historian Wilhelm von Dönniges especially gave advice to the king on political questions as well as on cultural matters.

The chances of success for Maximilian's policy diminished after Karl von Schrenck had taken Pfordten's place as minister (1859). Bavaria's support of the hereditary prince Frederick of Augustenburg as pretender to the duchies of Schleswig and Holstein (see SCHLESWIG-HOLSTEIN QUESTION) met with the opposition of all the other powers; but before the Austro-Prussian invasion of Denmark, Maximilian had died, in Munich, on March 10, 1864.

(K. O. v. A.)

MAXIMILIAN I (1573–1651), duke of Bavaria from 1597 and elector from 1623, was born in Munich on April 17, 1573, the son of the Wittelsbach duke William V and his wife Renée of Lorraine. Educated by the Jesuits at Ingolstadt, he succeeded to the ducal throne on his father's abdication in 1597. In Bavaria itself he broke the power of the (mostly Protestant) estates, which were not convened after 1612; and by strictly adhering to Catholicism he obtained Rome's assent to his control over the Bavarian church. With the whole apparatus of government in his own hands, he could create an efficient administration under a privy council, a well-trained army and a comprehensive law code. He was also a discriminating patron of the arts.

Maximilian's foreign policy was largely determined by rivalry both with the Calvinist Wittelsbachs of the Palatinate and with the Catholic Habsburgs of Austria. He also felt a vaguely patriotic dislike of foreign (mainly Spanish and Swedish) interference in Germany. These dispositions led him to a fairly consistent understanding with France, the chief opponent of the Habsburgs and the professed champion of the "German liberties."

When the Lutheran city of Donauwörth was outlawed by the imperial diet for failing to protect its Catholic minority, Maximilian undertook to execute the ban and then, for his insignificant exertions, drew up an account which the emperor Rudolf II could not pay. Maximilian therefore kept the town and re-Catholicized it, thus winning a foothold in Swabia. When the Protestant princes thereupon formed the union of Ahausen (May 14, 1608), Maximilian countered with the Catholic league (July 10, 1609). Next, on the death (1612) of his uncle Ernest, archbishop elector of Cologne and bishop of Hildesheim, of Liège and of Münster, he obtained these sees for his brother Ferdinand (who moreover became bishop of Paderborn in 1618); and in the War of the Cleves-Jülich Succession, the Catholic league's army under his general Tilly secured Jülich, Berg and Ravenstein in 1614 for Wolfgang William of Palatinate-Neuburg, husband of Maximilian's sister Magdalena.

When the Habsburgs tried to dominate the Catholic league, Maximilian seceded from it and in 1617 formed a new league without the Habsburgs. The emperor Ferdinand II had expressly to renounce all claims to the leadership of the league before Maximilian would come to his aid against the Bohemians (1619; see THIRTY YEARS' WAR). With French help Maximilian effected the neutrality of the Protestant union, and the league's army defeated the Bohemians (1620) and conquered the Upper and the Rhenish Palatinates (1622–23). Maximilian obtained the hereditary lands of the dispossessed Frederick V, together with the electoral dignity (1623), and kept Upper Austria in pawn (1620–28) for his real or alleged military expenses. He also took part in the Danish War, which was largely decided by Tilly's victory at Lutter (Aug. 27, 1626). But Maximilian's leading position was now threatened by the creation of an independent imperial army under Wallenstein. In concert with the other electors, he enforced Wallenstein's dismissal and the virtual disbandment of the imperial army (1630). The result was disastrous: the Swedes under Gustavus Adolphus promptly invaded Germany; the league's army, after the barren conquest of Magdeburg, was wiped out at Breitenfeld; Tilly himself was killed trying to defend Bavaria; and the Swedes entered Munich (1632). As Wallenstein, now generalissimo, did nothing to alleviate Maximilian's plight, Maximilian was instrumental in procuring his downfall (1634). The victory of Nördlingen liberated Bavaria from the Swedes (1634).

In return for his consent to the peace of Prague (1635), Maximilian forced the emperor to concede all that he wanted. He therefore took little part in further military actions and, on March 14, 1647, concluded an armistice with France and Sweden. Swedish reverses and an imperial attack on Bavaria soon made him abandon this new attitude, with the result that Bavaria was ravaged by the Swedes and French, who defeated the Bavarians at Zusmarshausen (May 17, 1648). The peace of Westphalia (Oct. 24, 1648) left Maximilian, thanks to his renewed co-operation with France, the electoral dignity and the Upper Palatinate, though he had to restore the Rhenish Palatinate to Frederick V's heir. Maximilian died at Ingolstadt on Sept. 27, 1651.

See F. Stieve, *Kurfürst Maximilian I. von Bayern* (1882); W. Goetz (ed.), *Die Politik Maximilians I. und seiner Verbündeten 1618–51*, 4 vol. (1907–48). (S. H. S.)

MAXIMILIAN II EMANUEL (1662–1726), elector of Bavaria from 1679, a prince of the house of Wittelsbach whose quest for dynastic aggrandizement obscured his reputation as a military hero, was born in Munich on July 11, 1662, the son of the elector Ferdinand Maria. He came of age to rule in 1680 and allied himself with the Holy Roman emperor Leopold I in 1683 for the war against the Turks, in which he made his name by capturing Belgrade in 1688. In the War of the Grand Alliance (1689–97) he took Leopold's side against France; and in 1692 Leopold induced Charles II of Spain to appoint him governor of the Spanish Netherlands. The elector set himself up in great splendour in Brussels, but his co-operation with William III of England achieved little success against the French.

Meanwhile, in 1685, the elector had married Maria Antonia of Austria, Leopold's daughter by Margarita Teresa of Spain and so a potential claimant to the succession of her uncle Charles II (see HABSBURG, *Tables II and III*). The electress, to whom her husband was flagrantly unfaithful, died in Vienna in Nov. 1692, having given birth to a son, Joseph Ferdinand. The elector could then expect that on Charles II's death this son would inherit the greater part of the Spanish dominions. When Joseph Ferdinand died (Feb. 6, 1699), the elector schemed to transform his governorship of the Spanish Netherlands into perpetual sovereignty.

For the War of the Spanish Succession the elector took France's side against his former allies. He now thought that the Wittelsbachs might supplant the Habsburgs in Germany. This prospect was shattered by the defeat of his army in the battle of Blenheim (1704). Dispossessed of Bavaria and, after the battle of Ramillies, driven also from the Netherlands (1706), he became a refugee at the French court. Bavaria, however, was restored to him under the peace (1714).

By Teresa Kunegunda Sobieska (1676–1730), whom he had

married in 1695, the elector had a daughter and eight sons, four of whom survived him. The eldest, Charles Albert (*see* CHARLES VII, Holy Roman emperor), was married in 1722 to Maria Amalia of Austria. The elector's last effort was to organize the Wittelsbach house-union of 1724, whereby Bavaria, the Palatinate and the Wittelsbach ecclesiastical princes concerted their action in Germany. Maximilian Emanuel died in Munich on Feb. 26, 1726.

MAXIMILIAN (MAX) OF BADEN, PRINCE (1867-1929), the last chancellor of imperial Germany, was born on July 10, 1867, the son of the grand duke Frederick I's brother Prince William of Baden (1829-97) and his wife Princess Maria Maximilianovna Romanovska. He married Marie Louise of Brunswick-Lüneburg (a titular princess of Great Britain) in 1900. From 1907 he was heir presumptive to the grand duchy of Baden, as his cousin the grand duke Frederick II (d. 1928) had no children. In the first years of World War I he devoted himself to the Red Cross and to work for the welfare of prisoners of war (on both sides). On

Oct. 3, 1918, when Germany was on the verge of collapse, he was appointed chancellor of the empire and prime minister of Prussia in succession to Georg Hertling. He hastily superintended the constitutional changes whereby a genuine parliamentary system was at last brought into being in Germany, began negotiations for an armistice and secured the dismissal of Erich Ludendorff—but too late to save the monarchy. When the emperor William II would give no definite answer to Max's demands that he should abdicate in the face of the danger of Communist revolution, Max finally himself announced the abdication of the emperor on Nov. 9, 1918. He then resigned the chancellorship to the leader of the Majority Social Democratic party, Friedrich Ebert.

Max continued to live in Baden till his death at Schloss Salem on Lake Constance, on Nov. 6, 1929. He had published *Völkerbund und Rechtsfriede* (1919), *Die moralische Offensive* (1921) and *Erinnerungen und Dokumente* (1927; Eng. trans. *Memoirs*, 1928).
